## PREFACE

Aviation today has become one of the dominant forces in this nation's economy and security.

The development of the airplane has exerted such a profound effect on national and world affairs that only time and the studious analysis of events by future historians will enable us to view the first 50 years of aviation in proper perspective.

At this time, it suffices to say that an ever increasing proportion of the world's transportation is being conducted by air. This trend can be expected to continue. Paralleling this peaceful contribution to world progress has been the development of the airplane as the most decisive military weapon in world history.

Because of the increasing capabilities of the airplane as a weapon of defense and as a vehicle of commerce, public understanding of aviation -its capabilities and its limitations-is of extreme importance.

The contents of this 1953 edition of Aviation Facts and Figures have been brought together from many different sources with the hope that they will serve as a reference work of value to legislators, administrators and managers in government and industry, writers and editors, analysts and students.

D. C. Ramsey, Admiral, USN (Ret.)<br>President, Aircraft Industries Association

## EDITORS' FOREWORD

This volume is not a work of original research. It merely brings together from hundreds of sources all the available facts which have been considered of importance or interest.

In using this book, readers should bear in mind two of its major limitations.

The first one is that much important information cannot be printed because of security reasons. Security restrictions are more severe today than they were during the Second World War. This has affected the chapters on production, military aviation, exports, training, and research and development. It has made impossible the preparation of a chapter on materials, knowledge of which is essential to a full understanding of aircraft production.

The second limitation lies in the lack of comparability among many of the tables shown in this book. Similar terms, such as "aviation," the "aeronautic industry," the "aircraft industry," the "airframe, engine and accessory industry," etc., often are used with different meanings. These differences may cause variations of billions of dollars between statistical tables apparently covering the same subject.

Here are some examples: Are guided missiles to be considered as pilotless aircraft-and do they therefore belong in the aircraft industry? The answer will affect statistics on the value of production by hundreds of millions of dollars.

Is the "component" industry part of the aircraft industry? A competent observer estimates that $1,600-1,800$ manufacturers with 600,000 employees make up the component industry. Although the effect of including or excluding this industry in a statistical table is evident, too often it is impossible to determine which practice has been followed. There is no consistent pattern.

Problems of proper classification and clear definition occur constantly, and are made more difficult because of the rapid changes in the industry. Even if they were solved, there would still remain the problem of getting agreed-upon classifications and terms used by the many different sources of data.

We would like to express our sincere thanks to the many individuals and organizations (both government and private) who have made this book possible through their freely given advice and assistance. The Air

Transport Association has been kind enough to review the chapter on Airlines for factual correctness.

Our particular appreciation is extended to Mr. Charles L. Black for editing the text, to Miss Teressa Smith, who helped in the collection, checking and production of the statistical tables, and to Miss Helen Mruk for her assistance in typing and proofreading.

This book is published in answer to the many requests for statistical information which are made to our Public Relations and Industry Planning Services. We hope that all who use this book will let us know their suggestions and comments so that future editions may be made more helpful.

610 Shoreham Building Washington 5, D. C.

November, 1953

## CHAPTER I

## PRODUCTION FACILITIES

The mobilization of the aircraft industry which followed the outbreak of the Korean War in June, 1950, required a broad-scale expansion of aircraft production facilities-land, buildings, machinery and equipment.

While many World War II facilities, created in an industry-wide expansion only a decade earlier, were still in existence, a substantial proportion had been made obsolete by technological advances embracing virtually every science and skill known to modern industry. There were new requirements for land, highly-specialized machinery and equipment -and even buildings.

## Special-Purpose Machine Tools

The heavier gauges, more critical tolerances and specialized forms of modern aircraft imposed, for example, the need for larger and more complicated machine tools. It was necessary to procure and place into service tools such as special-purpose milling machines, large stretchforming machines, giant hydraulic presses and other costly high-production machinery not economically practical for use on small peacetime orders.

## More Land Needed

Additional land frequently was necessary for the long runways required by modern jet aircraft, for the increased maneuvering space needed by high-speed planes, and for testing areas remote from urban centers.

## Modern Plant Requirements

Moreover, many of the plants suitable for World War II production or for non-aircraft manufacturing purposes were inadequate for the production of modern military planes. Airframe assembly today, for example, requires increasingly large plants, with higher ceilings, balconies, overhead cranes and wide bays. The production of some of the latest equipment installed in advanced airplane models requires facilities which are sound-proof, temperature-controlled and vibration-proof.

## Major Facilities Problems

The problem of acquiring additional plant space was not so great at the beginning of the Korean War, however, as was that posed by the
shortage of the new and complex machine tools essential for modern combat plane production.

When the Korean War started, more than 60 million square feet of floor space were being used for aircraft production, as compared to the 9.5 million square feet in operation at the beginning of 1939 when European orders triggered the American industry's World War II expansion. Moreover, in 1950 a number of large government-owned plants were either on so-called "standby status" or were leased to industry under terms which made possible a quick return to the government in case of need.

Acquisition of machine tools quickly became a major problem. Although generally better equipped than ever before, and possessing a reserve of general-purpose tools, the aircraft industry was not adequately supplied with the highly specialized machines required to produce the latest model aircraft and engines.

## Financing Facilities Expansion

As in World War II, the government offered tax amortization incentives to induce industry to use private capital for facilities expansion. In the case of manufacturers with a stable peacetime demand for their products, the effect of such tax amortization regulations is to postpone the payment of tax money. The tax savings during the emergency period amount to deferred levies which are recovered by the government after the emergency ends, provided peacetime business is sustained on a firm level.

During World War II, amortization provisions permitted manufacturers to write off facilities over a period of five years or, if the emergency lasted a shorter time, during the period of the emergency. Amortization provisions during the most recent build-up, however, stipulated that facilities expansion would have to be written off for tax purposes over a period of five years - even if the emergency conditions which brought about the expansion were of shorter duration.

Despite the increased risk to the aircraft industry posed by this change in government policy, the industry provided a much greater proportion of facilities expansion funds than was the case in World War II - 34.1 per cent as contrasted with 10.8 per cent.

At present, the scheduled expansion of aircraft production facilities is virtually completed, with floor space having approximately doubled and with most plants equipped with the specialized tooling required under current production programs.

## CHAPTER II

## PRODUCTION

Modern technology has few problems of greater complexity than those faced in translating blueprints and dollars into high-performance military aircraft. The production effort itself is tremendous-tremendous in dollars, tremendous in terms of employment, tremendous in pounds of aircraft that must be produced.

Although frequently described as a mass production industry-comparable, for example, to the automobile industry-the aircraft industry is confronted with production problems which are in many respects unique. These unique problems stem from the nature of the aeronautical product itself, from the emergency conditions under which production frequently must occur, and from the governmental regulations which circumscribe many of the production processes.

## Production Fluctuations

Throughout the industry's 50 -year history, aircraft production has been in fits and starts, with peaks of effort required during emergencies and war years and with deep production cutbacks in peacetime.

In 1939, when World War II broke out in Europe, a total of 5,856 aircraft (of which only 2,195 were military types) were produced in the United States. With orders from Europe, followed by President Roosevelt's call for production of 50,000 planes per year, military aircraft output increased from 6,019 in 1940 to a World War II peak of 96,318 in 1944.

The defeat of Japan brought about an almost overnight curtailment of production-and output fell to only 1,669 military planes in 1946.

When the Korean War began in June, 1950, some 215 military aircraft were being built per month in the United States. Today, the industry has largely completed a limited emergency expansion, and is producing military planes at the approximate rate of 12,000 per year.

## Rapid Aeronautical Progress

The history of the airplane has been one of continuing increases in performance and size, resulting in greater complexity and infinite precision in the manufacturing operation. With each advance, new techniques and methods, new tools and new processes have been made necessary. In most cases, this progress has been preceded by the necessity for
research and development in completely unexplored fields of human knowledge.

The advent of the jet engine is a current example of the way new developments in the aeronautical sciences are accompanied by problems which affect every element of the aircraft manufacturing process. When the jet powerplant made possible great increases in aircraft power ten years ago, it immediately brought with it the requirement for aircraft designs which would enable the efficient use of this power. New materials and new equipment had to be developed; and completely new production techniques and machines were necessary to build the resultant more complex aircraft.

Even after ten years of design and development, the full potential of the jet engine has not yet been realized-and additional design and production problems remain. A typical example is the problem created by the tremendous heat encountered at high speeds. The solution will require new designs, different equipment, more specialized machine tools and, in fact, a new basic metallurgy.

Other respects in which the aircraft industry differs from the conventional mass production industry include:
(1) The inadvisability of freezing designs. Aircraft designs can rarely be "frozen" to permit economy of production. Changes must constantly be made in order to keep pace with scientific and engineering advances. These changes mean re-work and delay and are costly-but they are necessary in order to maintain continuing superiority over advances in other parts of the world. As a result, production runs in the aircraft industry are small, and are never firmly established.
(2) Dependence on contracts. More than 90 percent of the aircraft industry's business is with the United States government. Unlike such industries as the automotive, which has millions of customers and can plan ahead for a reasonably certain mass market, the aircraft industry's work load has in the past been directly dependent upon national policy fluctuations dictated by changes in the international situation.

The instability of the work load creates problems in manpower and capital during periods of expansion and contraction.
(3) Need for development continuity. The need for continuity of management, research and development personnel, production facilities and production skill makes it necessary for the typical aircraft company to maintain large establishments even at the lowest points of the production curve. The basis for rapid advances in the aeronautical sciences lies in accumulated design, development and manufacturing experience, and the retention of production teams is in this respect more important
than the actual size of the industry at any particular period.
(4) Aircraft lead time. The production of modern military planes involves thousands of inter-related actions and months of time in assembling needed parts, materials and components. Some elements of production time are irreducible; others already have been shortened by manufacturers through continuing advances in manufacturing techniques.

The great complexity of the manufacturing process is one of many factors that make the production of modern aircraft a necessarily timeconsuming operation. Among other factors are: (a) the time required for military experts to establish strategic requirements and to translate these requirements into performance specifications, (b) the time required for design competitions and for contract awards, (c) the time required to build experimental models and test them, (d) the time required to prepare the production plan, a project that requires knowledge of the production lead time of each of the thousands of parts and materials that go into the finished aircraft, and (e) the time required to test, analyze (and modify, if necessary) the first production aircraft.
(5) Production in emergency periods. In a period of full or limited emergency, a number of unusual and frequently costly measures must be employed to achieve accelerated production. Among such emergency measures are (a) an increase in working hours, (b) an increase in the number of working shifts, (c) the employment and training of new and unskilled personnel, (d) the construction and acquisition of new production facilities, (e) the addition of more specialized high-speed tooling, (f) the use of "licensees," who engage in airframe and engine production for the emergency period only, then return to their previous peacetime production fields. These licensees are provided with designs, blueprints and manufacturing know-how by the basic aircraft and engine industry.

During periods of accelerated production, too, thousands of new subcontractors are brought into the production picture and an increasing share of the work is done with these "outside" firms.

To further speed production in an emergency, special modification centers are sometimes established. Normally, design changes are made on the production line when volume output is not the first priority. Use of modification centers increases the rate of production, but also increases cost.

N.A.-Not available.
a Data in this table do not include consumption by metals of metal mills engaged in fabricating metal products, or by non-manufacturing activities, such as construction, transportation, etc.
${ }^{6}$ Includes purchases and interplant transfers, but excludes data on production and consumption within the same establishment. Latter data, however, have been included in totals for 1949, 1950, and 1951. In 1949, quantity so included was 276,070 short tons; in 1950, 303,758. Thus, 1947 percentage is not strictly comparable with those of succeeding years.

- Withheld for security reasons on the advice of the Bureau of the Budget.
${ }^{d}$ Includes purchases and interplant transfers, but excludes data on production and consumption within the same establishment. Latter data, however, have been included in 1951 total. It is estimated that total tonnages produced and consumed did not exceed 2 percent of the tonnage purchased or received through transfer in either 1949 or 1950.
- Includes purchases and interplant transfers, but excludes data on production and consumption within the same establishment. Latter data in the amount of 43,431 and 25,298 short tons included in 1950 and 1949 totals respectively.
$f$ Includes purchases and interplant transfers, but excludes data on production and consumption within the same establishment. Latter data in the amount of 205,218 and 122,144 short tons included in 1950 and 1949 totals respectively.

## CHAPTER III

## LABOR

In June 1950, when the Communists attacked in Korea, national employment was at unprecedentedly high peacetime levels. The reserve manpower pool was low, and the civilian economy was booming.

The North Korean attack resulted in a sharp acceleration in preparedness efforts. The armed forces rapidly increased orders for military aircraft. To meet these high demands, the aircraft industry was called upon for the second time in a decade to enter upon a vast manpower expansion program.

## Peaks and Valleys in Aircraft Manpower

Over the years, employment in the aircraft industry has fluctuated greatly. At the start of the first World War, total employment was only 200. Four years later, when America was helping to win the "war to end wars," employment had skyrocketed to an estimated 50,000 men and women. By 1919, it was down to 4,200 and by 1921 to 2,000 .

This pattern was repeated several times during the following 32 years. The graph of aircraft employment shows a peak in 1929, when 18,600 persons were employed-and a valley in 1933 when only 9,600 were building planes.

During World War II, more Americans worked to build military aircraft than had been engaged in any single manufacturing effort in history.

In 1943, 1,342,500 persons were employed directly by aircraft manu-facturers-and more than 650,000 worked for aircraft subcontractors and suppliers. Between January 1940 and the end of 1943, aireraft prime contractors' employment levels increased 17 -fold.

This great work force produced more than 96,000 military aircraft in 1944-more military planes than had been built by any country in one year in world history, and more than had been built in the entire world prior to 1940.

In those war years, almost four of every ten persons in the industry were women. One of every 22 persons was an engineer.

The industry rose from 41st in rank among U.S. manufacturing employers to first.

## World War II Demobilization

Then came VE-Day-followed several months later by the atom-
bombing of Hiroshima and Nagasaki, and the Japanese capitulation.
The lack of a long-range aircraft procurement program led to the dismantling of the world's largest production machine-and the disintegration of its trained manpower teams.

In 1946, employment in the industry reached its postwar valley. A highly-trained nucleus of engineers and technicians staffed the plantsbut military orders reached dangerously low levels and the industry as a whole suffered heavy losses both in 1946 and 1947.

As a result of supplemental appropriations in 1948-down payment on a 70 -group Air Force-aircraft employment began to expand; but appropriations in fiscal 1949 and 1950 again were reduced to levels capable of supporting only a 48 -group force. Even so, by June 1950, aircraft and parts employment had moved from 16th to 11th among U.S. manufacturers.

## Aircraft Labor Shortages

Generally speaking, the industry experienced no severe shortages of labor of lower skills during the Korean buildup-except in critical areas which had comparatively tight labor situations prior to the outbreak of the war (for example, San Diego, Wichita and Hartford).

The acute manpower shortages developed in the highly-skilled lines: engineers, scientists, skilled craftsmen, technicians. Some shortages still persist in these fields.

## Supply of Engineers Dwindles

The greatest long-range manpower problem of the aircraft industry is the acute shortage of qualified engineers and scientists. Today, one in 11 aircraft employees is an engineer. This proportion grows larger constantly, as the need for research accelerates and increasingly complex military aircraft require greater numbers of engineering man hours.

With requirements mounting, an alarming factor in the engineering picture is the prospective decline in the rate of graduating engineering students. In 1949, for example, 47,000 engineers were graduated from the nations' engineering schools. In 1954, less than one-half this number are expected to be graduated.

## Statistics on Average Aircraft Worker

In the summer of 1953 , the average worker in the aircraft industry worked 41.5 hours per week, and his weekly earnings were $\$ 82.17$. In most cases, rate of pay was based on a job classification analysis which set a rate-range for each of the thousands of different jobs existing in the industry. Employees can advance within the rate-ranges through merit or length of service, or both.

Most employees receive a paid vacation and other fringe benefits, such as seven or eight paid holidays per year, insurance and sick benefits, and pension plans.

Only a few aircraft plants are unorganized. Most workers are affiliated with the International Association of Machinists (which entered the aircraft industry in 1934) or the United Automobile Workers (which received a charter covering aircraft workers in 1937).

## CHAPTER IV

## FINANCE

The aircraft manufacturing industry has had a history of rapid ex pansions in sales volume followed by sudden and sharp contractions. The increases in production and production facilities during recurring periods of national emergency have occurred with explosive force, when contrasted with the normal standards of industrial growth. In a matter of months in World War II, for example, the aircraft industry underwent an expansion of production and production capacity that would take manufacturers of commercial products many years to accomplish.

## Major Divisions of the Aircraft Manufacturing Industry

Although the airframe manufacturer designs the complete aircraft, he manufactures only the airframe-and then installs in this airframe many important component parts such as powerplants, fire control systems, radar and electronic equipment, etc. These component parts are known as Government Furnished Property (GFP) and are purchased by the military services, then furnished to the airframe manufacturer for installation.
(Since the value of GFP items represents more than 50 per cent of the cost of a completed aircraft, figures used below do not represent the total dollar amounts in the military aircraft production program. The financial problems involved, however, which are indicated by some of the balance sheet relationships in following tables, are applicable equally to the designers and manufacturers of these important component and accessory items.)

## Capitalization as Contracting Industry

The aircraft manufacturing industry is a contracting industry and is capitalized accordingly. This requires that the capitalization of companies (1) provide the credit stability and financial strength needed to support a high volume of sales and, yet (2), avoid the costly burden of overcapitalization during prolonged periods of low volume.

Furthermore, as is the case with other contracting industries, the
most economical and efficient method of financing production is for the customer (whether a commercial airline or the U.S. Government) to provide much of the financing needed for performance of the contract. If such were not the practice, and if contracting industries were capitalized to handle their infrequent peak volume, it would be necessary during years of low volume for the price of the end product to include the carrying cost of excess capitalization.

It will be noted (see Table 4-7) that during World War II the customer provided financing in the form of advances or contract deposits. During the Korean build-up, customer financing has been provided primarily through progress payments.

The data contained in the tables in this chapter cover the activities of the 12 major airframe manufacturers, based upon sales volume for each of the years from 1937 through 1952. Since the financial reports of the United Aircraft Corporation are released on a consolidated basis only, the activities of their Chance-Vought and Sikorsky Divisions are not included in the tables.

## Effect of Emergency Production Expansion on Financial Condition

The degree to which a suddenly expanded military production program affects the financial condition of the industry is shown by the following changes in the financial status of the 12 major airframe companies during the period 1950-1952.
(Dollar Figures in Millions)
$208.3 \quad 531.0$

1950 \$ 380.0
Net Worth
Working Capital 287.7 227.4 82.8 1,388.2 Working Capital Turnover (Times).- 4.8
Inventory-Net $\qquad$
Receivables
Plant
Sales Volume $\qquad$

1952 \$ 447.6 308.4
479.5 154.0 3,731.1 12.1

In this period (1950-1952) the total net worth of the 12 companies was increased by $\$ 67.6$ million, most of which represented reinvested earnings. All of this increased capitalization went into needed production facilities-brick and mortar, as well as machine tools and equipment.

Working capital in the same period increased $\$ 20.7$ million. With this modest expansion of working capital these companies were able to finance a $\$ 575$ million increase in accounts receivable and inventory. To accomplish this financing, working capital turnover was increased from 4.8
times per year to 12.1 times per year. A working capital turnover of this magnitude, in an industry which is manufacturing an exceptionally high unit-cost product with a 16 to 30 month manufacturing cycle, requires careful and close control both of the amount of working capital and the manner in which it is used. Under these conditions, the length of time between receipt of cash and its disbursement is extremely short and any disturbance in the flow of incoming cash would inevitably have a serious effect upon an individual company's-or an industry's-entire operations.

## Control of Accounts Receivable and Inventories

Control of the manner in which working capital is used requires that constant effort be exerted to keep the amount of funds tied up in accounts receivable and inventories at an absolute minimum and thus to retain in the form of cash sufficient amounts to meet vastly expanded payrolls and to keep on a current basis with mercantile creditors. As an example of the effects of such control, the $\$ 227.4$ million in accounts receivable at the end of 1950 represented an average collection period of 60 days, based upon a sales volume of $\$ 1,388.2$ million; by 1952 , the average collection period for accounts receivable had been reduced to 47 days.

Inventory figures shown in the table above and in this chapter are net, after deducting progress payments received from the customer during performance of the contracts. For the year 1950, progress payments received from the Government amounted to approximately 41 per cent of the gross inventory; at the end of 1952, they amounted to approximately 70 per cent of the gross inventory. The turnover of total gross inventory (not shown in the following tables) was 3.9 times in 1950 at the start of the production build-up, and had slowed to 2.1 times in 1952. Barring further stretchouts in the overall program, however, this inventory turnover will improve considerably for the year 1953 as the production program levels out and deliveries in volume are made to the military services.

## Aircraft Industry Earnings

The earnings of the aircraft industry are subject to a number of profit control measures, including renegotiation, price redetermination clauses, and various types of cost disallowances. The result of these various controls is shown by the average industry profit rate of 2.2 per cent on sales during 1952 for the 12 major airframe manufacturers. This rate is less than half of the average rate of profit on sales earned by all manufacturing corporations during 1952. This low rate of earnings is not unusual
(See Table 4-12, covering the years 1937 to date). The average earnings for the 12 major airframe manufacturers from 1943 to 1952 inclusive was 1.4 per cent on sales. This, according to Dun and Bradstreet reports, is the lowest rate of earnings on sales of any manufacturing industry for this 10 -year period. With these limited earnings, the industry's dividend policies have of necessity been conservative and the percentage of earnings paid out in dividends is well below the average of all manufacturing industries.

Table 4-8. Balance Sheets, Average Airframe Company, 1937-1952Continued
(Millions of Dollars)

Figures in parentheses indicate loss.

- Restricted cash is included in "Cash."
${ }^{b}$ To make this figure comparable to the figures of preceding years it has to be increased by $\$ 5,344,667$ to allow for changes in the accounting practice of one company.
- Revised.

Source: Aircraft Industries Association compiled from Moody's Industrial Manuals (1938-1944 editions). Data for 1944 to 1952 taken from individual company reports.

## CHAPTER V

## MILITARY AVIATION

Only five years after the hasty demobilization that followed World War II, the United States began an air power buildup designed to recreate military air strength for what was later called "an age of peril."

Under the impetus of war in Korea, and in the recognition that the Soviet Union possessed atomic capabilities, long-range objectives of the military were five-fold:
(1) To achieve strength adequate to deter Soviet aggression.
(2) To provide the capability for a powerful and sustained retaliatory offensive if such aggression should nevertheless occur.
(3) To achieve the ability to detect and destroy as many attacking aircraft and guided missiles as possible in event of attack on the United States or its free world allies.
(4) To create adequate reserves of equipment and personnel for commitment in the early and decisive stages of any possible future conflict.
(5) To build a mobilization base for rapid expansion of the military services and of their supporting industries under emergency conditions.

## Postwar Decline in Military Strength

The outbreak of the Korean War found the military air services of the United States at strength levels below those required by the nation's global responsibilities.

The precipitate demobilization which came on the heels of victory over Japan in 1945 ran counter to plans made by all the services for reducing the armed forces in an orderly fashion to levels considered the minimum allowable for national security.

Military plans were for 70 peacetime Air Force groups and proportionate Naval air strength. The headlong demobilization of 1945 and 1946, however, decimated the nation's air arms-and by 1946 the Air Force did not have even one operational group ready to defend the United States.

## The Air Power Reports

In 1947, the National Security Act gave air power equal organizational status with naval and land power.

In that year, too, the President-recognizing the peril to the nation of air weakness-appointed a commission of outstanding citizens to make
recommendations ". . . so broad in scope and purpose that they will assist in revising old policies and in framing new ones, and will serve as a guide for formulating a carefully considered national air policy." At the same time, a Congressional Aviation Policy Board came into being for the same purposes.

When their studies were published early in the following year, the nation had two primary documents, differing only in detail, that attested to the undeniable first-rank importance of aviation in the protection of the United States. The report of the President's Air Policy Commission called for an immediate buildup of the Air Force to 70 groups by January 1, 1950, and for adequate appropriations to modernize Naval aviation. Three months later, the Congressional Aviation Policy Board reached similar conclusions.

Both groups dealt at length with related problems that had long plagued the diverse elements in aviation. Aircraft production for the government has always been a stop-and-go proposition. The President's Air Policy Commission pointed out that a five-year procurement plan could save up to 20 percent or 25 percent in production costs, and recommended a series of five-year purchasing plans. The Congressional Board concurred. Both groups called for the development and construction of early-warning radar networks, a satisfactory airport program, and better navigational and weather reporting facilities. Together, these reports alerted the public to the abyss into which aviation had fallen.

The Congressional Board said:
"It is the judgment of the Congressional Aviation Policy Board that the capability of the United States most likely to discourage an aggressor against attack upon this nation, most effective in thwarting such an attack if launched, and most able to deal out retaliation to paralyze further attack, is air power."

## Air Power Funds Appropriated, Impounded

In the spring of 1948, the Supplemental National Defense Appropriation Act of 1948 was passed, providing funds to step up aircraft procurement, research, development and operations. The industry received new orders, designed to raise the nation's military air strength, but as 1948 rounded into 1949 a sizable proportion of the funds was impounded by Executive action-and many contracts were cancelled.

## The Limited Mobilization

The great debate over air power was resolved less by agreement on principles than by the exigency of war-the North Korean attack across the 38th Parallel. As the buildup got underway under the lash of war
in Korea, the military forces and the aircraft industry faced a multitude of problems that had not existed a decade earlier. The developments that grew out of World War II, and reached maturity in the years just after it had to do with atomic energy, jet and rocket propulsion, guided missiles and the new science of electronics. As continuing advances were made in solving these new aeronautical problems, it became apparent that air arms capable of stopping attacks and delivering A - and H -bombs to the heart of the enemy must be maintained in America so long as the threat of war exists.

## The Cost of Military Air Power

About ten cents of every dollar's worth of goods and services which this country produces goes to military aviation. The determination of the size of each fiscal year's appropriations, and of the manner in which these funds will be spent, is a time-consuming and complicated process.

The roles, missions and responsibilities of the miltiary services result from studies of the Joint Chiefs of Staff, following which the individual services determine the number of planes, airfields, personnel and other equipment required to accomplish these objectives.

With requirements determined, an estimate of financial cost is assigned to each of the force levels-and the development of these dollar amounts results in the detailed defense budget.

Months of military hearings, within the Services and the Department of Defense, follow-during which the budget is explained, defended, cut, adjusted, and changed. It is then presented by the President of the United States to the Congress.

At this point, additional hearings begin in Congress before Subcommittees and Committees; Conference Committees compromise differences between House and Senate. Finally, an Appropriations Bill is passed by the Congress. The amount finally appropriated frequently differs substantially from the amounts originally requested by the Services. In such cases, the Services must then re-program to operate within the limitations set by available funds.

Money appropriated in any one year usually must be "obligated" (although not necessarily spent) in the same fiscal year. With long leadtime items such as military aircraft, it is normal for expenditures to follow obligations by two to three years.

## Organizations of Wings, Air Groups

Air Force: The basic organizational unit of the United States Air Force is the "wing." A wing is comprised of a combat group and necessary administrative and service units. The number of airplanes in a
wing depends on its mission; for example, a group of heavy bombers has 30 planes, a medium bomber group has 45 , a light bomber group 48 , a day fighter group 75, an all-weather fighter group ©3. The USAF also operates separate squadrons for rescue, support and in-flight refueling.

Navy and Marines: Navy carrier air groups usually are composed of four fighter and one attack squadrons, and another unit comprising night fighters, minelaying aircraft, helicopters and other aircraft. Large battle carriers (C-VB's) have a complement of about 117 aircraft, Smaller Essex-class carriers (CV's) have about 91. Antisubmarine squadrons attached to light and escort carriers average about 23 aircraft and shore-based patrol squadrons have nine planes each. Marine fighter squadrons are assigned 24 aircraft.

Army: The United States Army has lightweight liaison aircraft and helicopters in its table of equipment for support of ground units. In 1952, the Army was reported to have about 1,600 planes and was planning to receive delivery on 1,000 to 1,500 light aircraft per year.

## CHAPTER VI

## AIRLINES

The U.S. commercial airlines in scheduled domestic and international service operate about 1,250 planes, half of them four-engined, and fly over 190,000 route miles. These airlines offer more lift capacity than the rest of the world's air carriers combined.

Today, these U.S. airlines are recognized leaders in the world. Their airplanes are considered the safest and most reliable equipment available. They fly more than half (excluding the U.S.S.R. and China) of the world's passenger-miles, cargo ton-miles and mail ton-miles.

Already, the domestic airlines carry more passenger-miles of revenue traffic than Pullman cars and if present trends continue they will, within a few years, carry more than railroad coaches.

## Speed and Cost

Wagon transport on the Philadelphia-Lancaster Turnpike (which was finished in 1794) moved at a snail's pace and at a cost of 13.5 cents per ton-mile. Today, with a much cheaper dollar, railroad freight moves for about one and one-half cents per ton-mile and travels a few hundred miles per day, while air freight crosses the continent in less than a day's time for about 20 cents per ton-mile.

A passenger v. ho took the stagecoach from Pittsburgh to Philadelphia in 1812 had to spend six days on the road and paid 27 dollars for the trip. In 1834 he could cover the distance by rail, canal and stage coach in less than four days for about $\$ 15$. Today, when the dollar is worth much less, the fastest train will take him there in six hours for $\$ 11.81$ by coach, or $\$ 18.25$ by parlor car. If he takes a plane he can make the trip in one hour and a half for $\$ 16.75$.

## Private Enterprise and Public Aid

Private enterprise has given the impetus to most of our development in transportation. Beginning with the private corporations formed to build the first turnpikes, private citizens and business organizations have provided much of the inventive genius, the production technology, the managerial drive and the capital that have given direction and strength to the development of the newer forms of transportation.

From the earliest days, however, the government realized that fast
and economical transportation was necessary for the economic growth of the country and for its protection; consequently, public enterprise has supplied a substantial part of the basic facilities over which private equipment has operated.

In the long run, each mode of transportation pays back more than the public aid put into it. Today, the railroads operate without government subsidy and highway users contribute through their gasoline and license taxes to the cost of maintaining highways. Civil aviation, still in its early stages of development, is going through the same cycle.

The first major use of the airplane was to carry the mail and for this reason the Post Office Department has played a major role in civil aviation history. The first air mail was carried in 1911; but it was not until 1917 that funds were appropriated for an air mail experiment. New York-Washington service began the next year. For seven years Government planes carried the mail. By 1925 private operation appeared feasible and the Kelly Air Mail Act created an economic basis for a civil airlines industry. Private capital was quickly attracted. By 1926, a number of airlines were organized and the first private carriers were in operation.

Since that time the airlines have been helped by government subsidy and by government-furnished airways service. These aids, like the ones to older means of transportation, have been provided because it was in the public interest to develop and encourage "an air transportation system properly adapted to the present and future needs of the foreign and domestic commerce of the United States, of the Postal Service, and of the National Defense." Every year the amount of the direct subsidy comprises a smaller percentage of the total operating revenue of the domestic and international airlines and the time appears not too far distant when the airlines will be self-supporting.

## Government Regulatory Bodies

Under the Civil Aeronautics Act of 1938, air carriers must obtain a certificate of "convenience and necessity" prior to engaging in scheduled air transportation.

These certificates are granted by the Civil Aeronautics Board, after investigating all applications and holding open hearings. The CAB regulates the economic aspects of United States airlines, promulgates safety standards, investigates accidents, and cooperates and assists in the development of international air tranportation.

The Civil Aeronautics Administration enforces civil air regulations; plans, constructs and maintains the Federal Airways System ; coordinates a national system of airports; and aids aviation education and training.

Airlines and the National Defense
America's air transport fleet is a major component of the nation's air power. About 300 four-engined airliners have been earmarked under a program establishing an air transportation reserve for transfer to overseas U.S. military operations on 48 hours' notice in case of an emergency. Such a transfer would give the military more than four times the tonmileage capacity it received from the airlines at the outbreak of World War II, yet would not seriously disrupt normal civilian traffic.

## CHAPTER VII

## UTILITY AIRPLANES AND HELICOPTERS

## Utility Airplanes

For every airliner there are about 35 personally-owned or businessowned aircraft operating in the United States.

Civil Aeronautics Administration records indicate that the total active civil aircraft fleet today numbers about 54,000 , of which the transport fleet of the airlines accounts for only about 1,500 . (Though CAA registrations on January 1, 1953, listed about 90,000 U. S. civil aircraft, surveys indicate that some 33 percent of these are not in active use.)

Most of the 54,000 active civil planes are light utility aircraft operated for business, industrial and agricultural purposes and, to a lesser extent, for pleasure and sport. A substantial number, however, are larger multi-engined aircraft; in fact, more multi-engined transports are owned and operated for business purposes alone (principally for executive transportation) than are operated by the airlines.

## Kinds of Utility Airplanes

There are four main types of utility airplanes:
(1) One- to two-place, having a gross weight of 1,500 pounds or less. Powered with 65 to 125 horsepower engines, these planes have speeds ranging from 70 to 125 miles per hour. In this group are found aircraft most often used for instruction, for agricultural purposes, and for sport flying.
(2) Three- to four-place, weighing from 2,200 to 2,700 pounds. Powered by engines of from 125 to 175 horsepower, the planes in this category are considered excellent cross-country aircraft, able to maintain cruising speeds of 110 to 140 miles per hour. Such aircraft are extensively used in all types of general aviation.
(3) Four- to five-place, having a gross weight of from 2,200 to 4,600 pounds. Powered by engines of from 175 to 300 horsepower, these planes can cruise at speeds of 140 to 200 miles per hour, and are generally called executive aircraft.
(4) Five- to nine-place, twin-engined light transports. Powered by 250 to 500 horsepower engines, these aircraft have a cross-country speed of from 150 to 200 miles per hour. They have four to seven hours' endurance on flights, and have instrumentation and radios enabling airlinetype performance and blind flight in marginal weather.

In addition to these types, there are several hundred larger multiengined aircraft in the civil fleet, comparable or identical to airline equipment. In most cases, these planes are used by corporations for executive transportation.

## Utility Airplane Usage

Utility-type aircraft are used in six principal ways:
(1) Business. A large number of utility planes are used for rapid transportation in connection with the operation of business. Ownership and operation are by businessmen themselves, or by corporations which maintain their own air fleets.
(2) Industrial. Increasing numbers of utility airplanes are flown for industrial purposes, such as power and pipeline patrol, geophysical exploration, aerial mapping and survey, forestry survey and patrol, etc.
(3) Agricultural. The utility airplane is used for two purposes by farmers and ranchers. Individual farmers and ranchers fly for transportation and for such tasks as personal aerial surveys in connection with planting crops, erosion control, etc. Commercial operators also use utility aircraft for dusting, spraying and the application of other pesticides, fertilizers, hormones and chemicals.
(4) Instructional. The business of teaching persons to fly and of improving the skill of pilots is largely conducted by airport base operators as part of their airport business.
(5) Charter. Many airplanes are maintained by aviation services for charter or for rent (much as cars are chartered or rented, either with or without an operator). A growing "air taxi" industry also uses a large number of utility airplanes.
(6) Pleasure or Sport. Light planes also are flown for pleasure and for sport. Once the largest single use for light airplanes, pleasure and sport flying is now the smallest.

## Production Levels

Monthly utility airplane production figures through August, 1953, show a steady increase during the current year over production in the comparable period of 1952. Based on the first eight months of production in 1953, total utility airplane output for 1953 should reach approximately $4,000-\mathrm{a}$ thousand more units than were built the preceding year, and about double 1951's production. Statistics on airplane use in 1952 point to a continued increase in business and agricultural flying.

## Helicopters

In the seven years since the first certificated U. S. helicopter was flown, the nation's manufacturers have produced approximately 3,000
helicopters. Although the industry's production since the outbreak of hostilities in Korea has been concentrated primarily on military types, with a resultant restriction on industry-wide information, it is generally understood that helicopter manufacturers have maintained backlogs of unfilled orders on the order of $\$ 500$ million over the past several years. Manufacturing Picture

Although at present only a small segment of the U. S. aircraft industry, six helicopter manufacturers are presently in active production on 15 models. Current helicopter industry employment is about 14,000 , and the annual helicopter industry payroll is approximately $\$ 52$ million.

Manufacturers report a wide variety of models in various stages of design, development or actual flight testing. These range in size from one- to 60 -place craft. The first of the so-called "flying cranes"-or heavy weight-lifting helicopters-is in an experimental stage.

Powerplants of the newer helicopter models include piston, gas generator, turboprop, and tip-jet units. Cruising speeds are expected to range from 75 to 170 miles per hour.
Military Use
The Korean War firmly established the utility of helicopters for aeromedical evacuation. By the end of the war, the Army alone had airlifted from the battlefield over 16,000 casualties. Helicopters also proved themselves in combat by moving combat troops and hundreds of tons of supplies over difficult terrain in incredibly short periods of time-and often were able to transfer personnel and material to commanding mountain heights inaccessible by other means of transportation. Because of its peculiar adaptability, the military services are placing increasing emphasis on helicopter development.

## Civil Use

In 1953, the first regularly scheduled helicopter passenger service was inaugurated on a restricted scale in the New York area. Inter-airport passenger service was begun between LaGuardia, Idlewild and Newark airports. Other helicopter mail operations in Los Angeles and Chicago continued to expand, but neither has yet added a passenger service.

In addition to the promising outlook for helicopter usage in carrying passengers and mail on regularly scheduled routes, the helicopter's ability to rise and descend vertically is expected to result in increasing specialized civil and industrial use.

The airlines may well be among the industry's major civil customers, according to preliminary reports of a special Air Transport Association Helicopter Committee studying this craft's adaptability to scheduled operations. Near year's end, one airline, National, had announced the purchase of its first helicopter.

## CHAPTER VIII

## EXPORTS AND AID TO FOREIGN COUNTRIES

Since 1950 , more than 4,000 military aircraft have been shipped overseas to U. S. allies under the Military Defense Assistance Program, and a few civil planes and equipment have been sent to foreign nations by the Mutual Security Agency.

In addition to providing these complete aircraft to allied countries, the United States government has underway a program to foster European military aircraft production. This program, designed to develop native production capacity and self-sufficiency, calls for production in Europe of 1,725 military aircraft, at a total estimated cost of about $\$ 580$ million, over the next several years.

The current aid program in many respects follows that of World War II, when the U. S. aircraft industry shipped 45,000 airplanes to members of the United Nations. Lend-lease shipments of aeronautical products exceeded eight billion dollars in value during the war years.

## Exports Essential to Industry Welfare

Only a few industries export a greater percentage of their production than does the civil aircraft industry. The average for all industries is less than 10 per cent, compared with 25 per cent for the U. S. civil aircraft industry in normal years.

Military aircraft exports vary from extremely low levels in some peacetime years to as much as 50 per cent of total production in others.*

Purchases by foreign nations of U. S. aircraft and equipment in the past have been of great importance to the American aircraft industry. In 1914, about 25 percent of the output of the small U. S. aircraft industry was sold abroad. During the depression year of 1933, in another instance, exports of $\$ 9$ million worth of aeronautical equipment (out of a total production of $\$ 26.5$ million worth of aircraft and parts) did much to save several companies from financial ruin.

## Competition for Foreign Markets

U. S. aeronautical exports are several times larger in dollar volume than those of the nearest foreign competitor, the United Kingdom. British exports, however, represent a greater proportion of British aircraft production.

[^60]The British aircraft industry receives greater assistance from its Foreign Office representatives in promoting aircraft sales than does the American industry. Even in the case of military aircraft exports, U. S. government restrictions both on type of aircraft and on permissible destination of shipments have been far stricter than those of the British.

The major assistance received by the American aircraft industry from the government in the export field is obtained from reports filed by embassies, legations and consulates.

A shortage of dollar exchange in many parts of the world since World War II also has made the export problem difficult for U. S. manufacturers.

Despite these handicaps, it is anticipated that total exports of aeronautical products (Military Defense Assistance Program, Foreign Operations Administration, and regular commercial and utility aircraft shipments) will approximate $\$ 900$ million during 1953.
Sources of Data
The major source for statistics on aeronautical exports is the Foreign Trade Division of the Bureau of the Census. Industry and government work together in preparing and classifying statistics on commodities exported from the United States.

Other sources of statistical information on aeronautical exports are the Export Service of the Aircraft Industries Association (for utility aircraft), the Foreign Operations Administration (formerly Mutual Security Agency), and the Office of Miiltary Assistance of the Department of Defense.

Since 1949, few dollar figures for aeronautical exports by classes have been published. Detailed export figures for military, cargo and used transport aircraft, for all engines of 400 horsepower and over, for propellers, instruments and all accessories, and for spare parts and aircraft ground-handling equipment have been lumped into a "Special Category'" for security reasons. Only recently has a total dollar figure for all aeronautical exports been made available.

## CHAPTER IX

## FOREIGN AVIATION DATA

## Manufacturing

The United States aircraft industry currently is producing more aircraft per year than any other nation, with the possible exception of the Soviet Union.

Although few facts about aircraft facilities and production in Iron Curtain countries are available, United States military observers have reported that the Soviet Union has a large and competent aircraft industry. Its production is believed to be numerically as great, or possibly greater, than that of the United States.

Reliable statistics on aircraft production even in the free world are difficult to obtain. The United Kingdom, however, with an aircraft industry employment of more than 200,000 , is generally believed to be the world's third-ranking aircraft producer.

Canada, France, Italy, The Netherlands and Sweden have sizeable aircraft industries, and smaller industries exist in Argentina, Australia, and Belgium. Other aircraft-producing nations in the free world include Brazil, Chile, Denmark, Finland, India, Norway, Portugal, Spain, Switzerland and Turkey.

## Exports

United States civil aeronautical exports are the world's largest (see Chapter VIII). With the possible exception of the Soviet Union's exports to satellite nations, on which no statistics are available, the only other nations with significant export volume are the United Kingdom and Canada.

## Utility Aviation

The development of so-called utility aviation in foreign nations has not been so spectacular as in the United States. While light aircraft are flown for utility purposes in most of the nations of the world, the number of such craft is not substantial. In England, for example, less than 1,000 airplanes fly for charter, private and business use, training, cropspraying, and other utilitarian purposes. Approximately the same number of utility planes are in operation in Canada. Smaller numbers operate in the countries of continental Europe and Latin America.

## International Air Transport

In 1952 , the scheduled airlines of the world flew slightly more than a billion miles, carrying 45 million passengers more than $241 / 2$ billion passenger-miles.

This traffic volume represents an increase of more than five times as many miles flown, 17 times as many passengers carried, and 28 times as many passenger-miles as in the year 1937.

## Freedom of the Air

Today, although freedom of the air space above the high seas is generally accepted, all nations have complete sovereignty over air space above their own territory. They may exclude or admit foreign aircraft on such terms as they see fit.

Despite these barriers to the free use of air space, however, the years from 1919 to the outbreak of World War II in 1939 constituted a great pioneering period in the development of air commerce. By 1939, practically every international air route of importance had been pioneered. The world's air routes were in operation and international air commerce had become reality.

## International Agreements

Agreements between nations were essential to the growth of air commerce. The first international air navigation agreement was signed in 1913 between France and Germany. Six years later, the first general air convention took place in Paris with 26 nations represented. In 1928, 11 American countries, which had not signed the Paris Convention in 1919, met and ratified the Habana Convention. Both the Paris and Habana agreements covered safety and technical matters, but neither provided for the establishment of commercial air routes.

Not until the Chicago Conference of 1944 was an international aviation assembly able to resolve more than technical questions. The International Civil Aviation Organization, with headquarters in Montreal, was established as a result of this meeting. ICAO's activities deal not only with technical but also with the economic, legal and some financial aspects of the orderly growth of civil aviation throughout the world.

The International Air Transport Association, an organization of international air carriers, works closely with ICAO and provides an agency for collaboration among international air transport enterprises.

## CHAPTER X

## AIR TRAFFIC FACILITIES

Although accurate figures on the investment in U. S. airports have not been maintained, best estimates place the acquisition cost of the more than 6,000 civil airports in the nation at about four billion dollars.

An additional approximate six billion dollars has been spent for acquisition of military airports.

## Growth of the Nation's Airports

Until 1927, nearly all airports and landing fields in the nation were provided by the government for its air mail service (See Chapter VI).

The rapid expansion of aviation activity following Lindbergh's flight to Paris in 1927, however, brought profound changes-and a rapid growth in the number of private and municipally-owned airports. Municipal rivalry and competition for airline services helped to encourage airport construction without Federal assistance.

With the depression, and the collapse of private and municipal investments in airports, Federal aid was again instituted in 1933. By the end of World War II, with its increased tempo of air traffic, total Federal expenditures for civil airports aproached 750 million dollars.

In 1946, the continuing need for airport improvements was recognized by the Federal Airport Act of that year, which established a longterm program for Federal airport aid. Less than $\$ 200$ millions have been spent on the program to date.

## Airport Characteristics

As late as the 1920 's, 100 -acre sod fields with 1,500 feet cinder or gravel runways were sufficient to handle early model slow-landing airplanes.

By 1925, however, transport landing speeds reached about 50 miles per hour, and today they have reached approximately 100 miles per hour, bringing increasing requirements for stronger and longer runways and for larger airports.

As weight and landing speeds continue to rise, stronger and larger runways, taxiways, and aprons will be needed.

Present minimum runway requirements for airplanes with 100-mile-per-hour landing speeds are roughly 6,000 feet. Unless landing and braking characteristics are improved, jet airliners of the future will land
at 120 to 130 miles per hour, and probably will require runways on the order of 8,400 to 10,000 feet.

## Federal Airways

A system of aerial highways, known as Federal Airways, today connects all major cities in the United States. More than 72,000 miles of airways are marked with electronic navigational aids (beams, beacons, or modern omni-ranges) designed to transmit signals enabling airplanes to maintain their proper course and to know their positions as they fly.

## The Common System

The problems of air navigation center around instrument weather, when pilots must guide their aircraft accurately in three dimensions with nothing visible outside-and must have the ability to leave cruising altitudes and descend at speeds on the order of 140 miles per hour to the runways at the airports of their destination.

Many navigational instruments help make this possible. They include radio ranges (VOR) which tell a pilot where to fly; fan markers, which are like road signs, telling the distance to the destination; and direction finders which relate the bearing of the plane to the known location of a given radio station.

To improve safety and reliability, additional aids are provided through traffic control instructions from communications stations and traffic control centers along air routes. At present, transmission of these instructions requires communication with the ground by two-way radio; in the future, automatic equipment will furnish pilots with these trafficcontrol instructions.

By 1963, a nationally-integrated system of airways sufficient for the needs of America's air commerce and military aviation is expected to be fully operational. This airways system-called "The Common System"was developed by a joint group of government and industry experts, and will provide navigational equipment and procedures adequate for the higher-density air traffic expected in future years. It is now in partial operation.

## CHAPTER XI

## TRAINING

Behind America's aviation leadership are men-men who push back the frontiers of knowledge, and men who apply what has been learned to the design and production of more advanced aircraft. There are engineers, draftsmen and workers. There are highly-skilled crews who fly the nation's commercial and military aircraft. There are skilled technicians who maintain and direct air traffic. There are managers in the aircraft and air transport industries, in the military, and in the civil services of the government who plan and guide America's gigantic aviation effort.

Education and training, which assure a constant and highly qualified supply of personnel, are of crucial importance to the maintenance of American aviation leadership.

## Military Training

During World War II, more than 160 civilian schools were under Army Air Force contract to train flying and technical personnel. To a lesser degree, the Air Force employed this system of contracting with civilian schools during the early days of the Korean War.

At present, however, the Air Force has discontinued its use of civilian schools for other than primary flying instruction, and as a result most training schools are faced with serious economic problems.

In 1950, pilots were being trained for the Air Force at an annual rate of 3,000 . With the advent of the Korean War, this rate was increased to 4,000 per year, then to 7,200 per year-and in 1952 and 1953, inereases to 10,000 and 12,000 were under consideration.

Security restrictions prevent disclosure of the current rate at which military pilots are being produced; however, the demand for trainees exceeds the supply of qualified applicants.

## Industry and Airline Training Programs

The aircraft manufacturing industry, which has been repeatedly faced with shortages of skilled personnel, undertakes apprentice and inplant training programs during most periods of emergency expansion. In addition, a number of companies have programs under which they underwrite all, or a portion of, the tuition costs for personnel attending outside technical schools and colleges.

The nation's airlines operate flight and ground schools for the orientation and training of new employees, and for maintaining a high level of personnel efficiency.

## CHAPTER XII

## RESEARCH AND DEVELOPMENT

The airplane of today and the airplane or the guided missile of tomorrow are the end products of the interplay of many forces and pur-suits-scientists exploring the unknown, engineers using the findings of the scientists in solving practical problems, military experts defining the minimum performance of a plane that does not yet exist, purchasing departments ordering materials, production engineers scheduling the flow of a production line and hundreds of others doing their assigned parts.

## Pure or Basic Research

At the basis of all of our accomplishments is what we know about the laws of nature. Even the best equipped engineer can not do more than apply the knowledge provided him by the pure scientist. The fostering of pure science, the expansion of our knowledge of natural forces, is therefore a must for aviation.

Basic, fundamental, or pure research sets the pace of technical progress.

Basic research has to do primarily with the discovery of new facts about nature and with finding and developing principles. Its aim is the advancement of the frontiers of knowledge and the collection of basic information-in many cases guided solely by the curiosity and personal interests of the individual worker and not by the desire to obtain a specific result.

Basic aeronautical research is being conducted mostly by the National Advisory Committee for Aeronautics which was created in 1915. The Committee's research programs have the long range objective of acquiring the new scientific knowledge essential to assure American leadership in aviation. Beyond this, the NACA has the immediate objective of solving some of the more pressing problems resulting from aircraft design concepts.

Most of the research problems are assigned to NACA's own laboratories. Problems of flight propulsion go to the Lewis Flight Propulsion Laboratory at Cleveland. Most aerodynamic research is done at Moffett Field, California. Other research on aerodynamics, structures, hydrodynamics and other problems is done at the Langley Aeronautical Laboratory in Virginia.

These and other NACA installations employ about 7,600 persons.
To supplement the work carried on by NACA facilities, NACA and the military services sponsor and finance a coordinated program of research at a score of non-profit and educational institutions.

## Development, or Applied Research

Applied research, or development, is the intricate process by which new knowledge is used by the forces of engineering and industry.

Application of the results of basic research to the design, development, and production of improved aircraft is a function of the aircraft industry. The industry's task is the design and production of aircraft with a specified performance-so fast, so far, so high, so much capacity. Usually such requirements are generated by the using agency, be it military or civil.

The engineers prepare designs to meet these performance specifications. If the design proposal is approved, an experimental model is built to test the feasibility of the approach. Production specialists and design engineers work closely together to make sure that the model can be produced efficiently if ordered into quantity production. Normally a new plane is ordered in quantity only after it has been fully engineered and tested in sample numbers.

Evaluation of military aircraft and equipment is the function of the military services. They study and apply the techniques necessary to get the most out of the new aircraft or equipment.

## Measuring the Research and Development Effort

At the beginning of the Second World War the annual outlay for all research and development in the United States was well below one billion dollars.

In 1952 it had risen to more than 3.5 billion dollars. About one half of this money came from the Federal Government.

Only about one-fourth of the government's research and development work was performed in government-owned installations. The rest wentto industry, universities, research institutions, etc.

Research and development expenditures by the aircraft industry alone in 1951 (the only year for which the information is available) totaled more than 400 million dollars. About six of every seven dollars spent on aircraft research and development in that year came from Federal funds.

In January 1952 the aircraft industry employed more than 20,000 of the 90,000 professional research engineers and scientists, and 50,000 of the 220,000 total research personnel employed by American industry.

A serious shortage of qualified professional research personnel was felt during the period of expansion of aircraft production following the outbreak of hostilities in Korea. A shortage still exists. For the United States as a whole, the shortage of engineering graduates at the end of 1952 was estimated to be about 100,000 .

## CHAPTER XIII

## AVIATION AND OTHER MEANS OF TRANSPORTATION

The competitive American transportation system offers a variety of passenger and freight transportation unparalleled in the world. Passengers can travel by automobile, bus, rail, air and-where availablewater. Similarly, shippers can send freight by rail, water, truck or air. Producers and users of petroleum products have the additional choice of pipeline transport.

This variety of competitive transportation media contributes to better living, economic growth, and the military strength of the nation.

The overall result is an enormous increase in the use of all forms of transportation. A hundred years ago, the average citizen traveled little. Even in 1916, the golden age of the railroad, the average travel per person in America was only 352 miles per year. Today, the average person travels more than 3,000 miles per year, and all indications are that average annual travel will continue to increase.

The importance of transportation to the economy of the United States is brought out by the fact that all forms of transportation contribute about five percent of the total national income.

## Air Transportation Is Increasing

Today, aviation provides high-speed transportation, at reasonable cost, between major communities which are two hundred miles or more apart. Airlines already carry a sizeable percentage of all inter-city traffic, and present forecasts leave little doubt that aviation's share of such traffic will be greatly expanded in the near future.

## Competitive Fares

The Air Transport Association reports that in terms of the 1939 dollar, domestic trunkline passenger transportation costs 40 percent less than 14 years ago-or less than three cents a mile.

In 1926, airline travel per mile cost three and a half times as much as rail coach. Today, scheduled air coach costs only 60 percent more than rail coach, and non-scheduled air coach costs only 20 percent more. Comparative air and rail costs are even closer than the above figures indicate because (1) airline mileage between cities is, on the whole, 10 to 20 percent shorter than rail mileage, and (2) the value of time saved by air travel.

## Safety of Transportation

The National Safety Council, recognized authority in the field of safety, uses two criteria for the measurement of transportataion safety:
(1) The first measure is the total number of deaths-passengers, pedestrians, and others-caused by the various means of transportation per hundred million passenger-miles traveled. By this yardstick, the airlines' record is the best of all forms of transportation.
(2) The second measure is the number of passenger deaths per hundred million passenger-miles. By this yardstick, airline safety is superior to passenger automobiles and taxis, but below that of railroad or bus travel. In 1952, the U. S. scheduled domestic air carriers established a safety record of 0.38 fatalities per hundred million passenger-miles. This compares favorably with 1.3 in 1951 and 1.1 in 1950, the previous record year.

A total of more than 33,000 persons were killed in 1952 by automobile, railroad, bus and air transport accidents in the United States. Passenger cars and taxis accounted for 31,500 of these deaths, railroad passenger trains for 1,163 , busses for 610 , and scheduled airliners for 67 .

| 1945 | 6,694 | 3,691 | 1,753 | 54 | 678 | 518 |
| 1946 | 11,648 | 8,403 | 1,957 | 106 | 616 | 566 |
| 1947 | 14,876 | 11,619 | 2,000 | 119 | 580 | 558 |
| 1948 | 16,867 | 13,468 | 2,123 | 133 | 577 | 566 |
| 1949 | 19,274 | 15,995 | 2,094 | 151 | 513 | 521 |
| 1950 | 22,570 | 19,353 | 2,084 | 174 | 446 | 513 |
| 1951 | 22,104 | 18,690 | 2,134 | 231 | 500 | 549 |
| 1952 | 22,509 | 18,959 | 2,187 | 272 | 536 | 555 |

Note: The figures shown represent expenditures for consumer use only. They do not include business and government use which makes up about two-thirds of airline passenger revenue and probably a similar percentage of Pullman revenue.
a This is made up of expenditures for new cars, tires, tubes, gas, oil, repair, tolls, insurance, etc.
${ }^{6}$ This is made up of expenditures for streetcars, subways, taxis, commutation tickets, and ferries.

- Excludes commutation but includes sleeping and parlor cars and tips.
${ }^{d}$ Includes inter-city bus, waterways, baggage transfer and luggage.

[^0]:    a Data represent totals for the 12 largest airframe companies from point of view of sales in each year. The composition of the 12 companies may vary from year to year. Due to the release of only consolidated data by United Aircraft Corporation, it has been impossible to consider for inclusion in this table the activities of the latter's Chance Vought and Sikorsky Divisions.

    Source: Aircraft Industries Association, compiled from individual company reports.

[^1]:    N.A.-Not available.
    a The classification is determined by the activity which accounts for the largest percentage of total receipts. During the war years some non-aircraft companies, such as General Motors Corporation, may have been classified as aircraft manufacturers.
    ${ }^{b}$ Includes intangible assets.
    Source: Treasury Department, Bureau of Internal Revenue; unpublished data.

[^2]:    ${ }^{\text {e }}$ Estimate by Aircraft Industries Association of Air Force and Navy obligations since Korea. (Exeludes funds for guided missiles, electronics, and Air Force Heavy Press Program.)
    a Cost of manufacturing facilities authorized July 1940-June 1945.
    ${ }^{6}$ This is the total processed by the Aircraft Division of the National Production Authority. The difference between the 1204 million dollars shown here and the 908 million dollars shown in Tables 1-9 and 1-10 is due to applications either still pending with the Defense Production Administration on March 1, 1953 or denied by it.

    - Totals of Tax Amortization Certificates for Land, Buildings, Furniture, and Miscellaneous processed by Aircraft Division of National Production Authority as of March 1, 1953.
    ${ }^{d}$ Totals of Tax Amortization Certificates for Plant Equipment, Machine Tools, etc., processed by Aircraft Division of National Production Authority as of March 1, 1953.

    Sources: 1940-1945: Civilian Production Administration, Industrial Statistics Division, "Wartime Manufacturing Plant Expansion, Privately Financed, 1940-1945."

    1950-1953: National Production Authority, Aircraft Division; unpublished data.

[^3]:    N.A.-Not available.
    a Value of facilities authorized.
    ${ }^{b}$ Value of Requests for Tax Amortization received by the Aircraft Division of National Production Authority as of March 10, 1953.

    Sources: Surplus Property Administration, Report to the Congress, "Aircraft Plants and Facilities", January 14, 1946, p. 40.

    National Production Authority, Aircraft Division; unpublished data.

[^4]:    a Includes only projects estimated to cost $\$ 25,000$ or more for period July 1940-December 1944; also includes projects financed by British Government.
    ${ }^{5}$ Includes Federal cumulative obligations and scheduled private expenditures for period 1950-1953; does not include funds for guided missiles, aviation electronic equipment, and the Air Force's Heavy Press Program.
    Sources: Second World War: War Production Board, letter of May 12, 1945.

[^13]:    - For an aircraft already in production; time elapsing between placement of re-order and delivery of first airplane.

    Source: Eighty-Third Congress, House of Representatives, Hearings Before the Subcommittee on Appropriations on the Department of the Navy Appropriations for 1954, p. 761.

[^14]:    a Includes a small undistributed amount.
    ${ }^{6}$ Less than $\$ 50,000$.
    Source: Cunningham, William G., "The Aircraft Industry, A Study in Industrial Location," 1951, p. 202.

[^15]:    N.A.-Not available.
    a Includes proprietors and firm members in earlier years.
    ${ }^{\text {b }}$ Before 1947 the figures show "Wage earners." In 1947 the definition was changed to "Production and related workers."

    - This line and all following lines include data for aircraft engine manufacturers which are not available for prior years.

    Sources: Bureau of the Census, "Census of the United States, Manufactures;" 1919, 1929, 1939.
    Bureau of the Census, "Biennial Census of Manufactures," 1921-1937.
    Bureau of the Census, "Census of Manufactures, 1947."
    Bureau of the Census, "Annual Survey of Manufactures," 1949 and 1950, 1951, 1952.
    Bureau of the Census; unpublished data.

[^16]:    a Wage earners in the aircraft, engine, propeller and parts industry, according to the Census of Manufactures.
    ${ }^{b}$ Total employment in the aircraft, engine, propeller, and parts industry according to figures collected by the Bureau of Labor Statistics and published by Civil Aeronautics Administration.

    - Estimated by the Bureau of Employment Security on the basis of all workers covered by Unemployment Insurance Laws in the aircraft, engine, propeller, and parts industry.

    Sources: 1939: Bureau of the Census, "Census of Manufactures, 1939."
    1943: Civil Aeronautics Administration, "U. S. Military Aircraft Acceptances, 1940-1945," pp. 188193.

    1950 and 1958: U. S. Department of Labor, Bureau of Employment Security.

[^17]:    N.A.-Not available.

    Source: Bureau of Labor Statistics. This is a series that has been revised in 1953. It replaces figures previously published.

[^18]:    est.-Estimated.
    a Includes "Special Purpose" and "Modification Centers."
    ${ }^{\circ}$ Mid-month employment.
    Note: These are the best available figures on how many people were actually engaged in aircraft production during the Second World War. The "On Site" figures are lower than the totals given under "Employment in the Aircraft and Parts Industry" probably because employment in plants which produced parts but which were not prime contractors is not included. The "Grand Total," on the other hand, includes estimates for the aircraft emloyment of all manufacturers contributing to aircraft production.

    Source: Civil Aeronautics Administration; "U. S. Military Aircraft Acceptances, 1940-1945," pp. 10 and 11.

[^19]:    N.A.-Not available.
    a This line and all following lines include data for aircraft engine manufacturers which are not available for prior years.
    ${ }^{b}$ In recent years "salaries" include some payments to employees in construction, distribution, etc.
    Sources: Bureau of the Census, "Census of the United States, Manufactures": 1919, 1929, 1939.
    Bureau of the Census, "Biennial Census of Manufactures," 1921-1937.

    Bureau of the Census, "Annual Survey of Manufactures," 1949 and 1950, 1951, 1952.
    Bureau of the Census; unpublished data.

[^20]:    Sources: 1942-1943: Bureau of Labor Statistics, "Wartime Development of the Aircraft Industry,"
    Bulletin No. 800, p. 8.
    1947: Bureau of the Census, "Census of Manufactures, 1947, Aircraft and Parts," p. 3.
    1949 to date: Bureau of Labor Statistics, "Employment and Payrolls" (Monthly). Brought up to date by BLS.

[^21]:    N.A.-Not available.

    - Less than 05.
    ${ }^{6}$ Preliminary.

[^22]:    N.A.-Not available.
    a Figures on number of workers involved may include some duplicate workers if the same workers were involved in more than one stoppage during the year.
    b Man days idle as a result of a strike which began in the preceding year and continued into 1931.
    c In addition to the figures shown there were at least 54 strikes involving 106,993 workers and causing 242,478 man days of idleness, in plants manufacturing aircraft and aircraft parts but classified according to prewar products, in other industries. Most of these were in plants which normally manufacture automobiles and automobile equipment.
    ${ }^{d}$ From 1945 through 1952 figures have been rounded.
    Source: Bureau of Labor Statistics, Division of Wage and Industrial Relations; unpublished data.

[^23]:    Note: Department of Labor rounds figures to three significant places. Hence, certain subtotals above will not add up to totals.

    Source: Bureau of Labor Statistics, Division of Wage and Industrial Relations, letter of April 10, 1953.

[^24]:    a The injury-frequency rate is the average number of disabling work injuries for each million employeehours worked.

    A disabling work injury is any injury occurring in the course of and arising out of employment, which (a) results in death or any degree of permanent physical impairment, or (b) makes the injured worker unable to perform the duties of any regularly established job, which is open to him, throughout the hours corresponding to his regular shift on any one or more days after the day of injury (including Sundays, days off, or plant shutdowns).

    The severity rate is the average number of days lost as a result of disabling work injuries, for each 1,000 employee-hours worked. The computations of days lost include standard time charges for fatalities and permanent disabilities.
    ${ }^{6}$ Included with "Aircraft."
    Source: Bureau of Labor Statistics, "Work Injuries in the United States During 1950"; brought up $t$ ) data from BLS files.

[^25]:    Figures in parentheses indicate loss.
    NA-Not available.
    ${ }_{a}$ Including engines.
    ${ }^{6}$ The classification is determined by the activity which accounts for the largest percentage of total receipts. During the Second World War some major automotive corporations such as General Motors Corporation may have been classified as aircraft manufacturers.

    - Preliminary data.

    Sources: Treasury Department, Bureau of Internal Revenue; unpublished data.
    Treasury Department Information Release No. H-124, May 20, 1953.

[^26]:    a Total for last three quarters of 1948 only.
    Source: Bureau of the Census, "Facts for Industry", Series M42D (Quarterly).

[^27]:    a Due to the reporting of subcontracts both by the prime contractor and the subcontractor, both of which are airframe producers, there is some duplication in these figures on value of backlog. As of June 30, 1953 the duplication amounted to $\$ 330$ million.
    Source: Bureau of the Census, "Facts for Industry", Series M42D (Quarterly).

[^28]:    cr-Credit.

[^29]:    a Restricted cash is included in "cash."
    ${ }^{\circ}$ To make this figure comparable to the figures of preceding years it has to be increased by $\$ 64,016,000$ to allow for changes in the accounting practice of one company.

    - Revised.

    Source: Aircraft Industrles Association, compiled from Moody's Industrial Manuals (1938-1944 editions). Data for 1944 to 1952 taken from indjridual company reports.

[^30]:    a One company changed its accounting procedure in 1949. Current assets are therefore shown above in two ways: the first line for 1949 is directly comparable with preceding years; the second line for 1949 is based on the new accounting procedure and is therefore not comparable with preceding years.
    ${ }^{b}$ Revised.
    Source: Aircraft Industries Association, data taken from individual company reports.

[^31]:    Figures in parentheses indicate deficits.
    a Restricted cash is included in "cash."
    ${ }^{b}$ To make this figure comparable to the figures of preceding years it has to be increased by $\$ 64,016,000$ to allow for changes in the accounting practice of one company.

    - Revised.

    Source: Aircraft Industries Association, compiled from individual company reports.

[^32]:    ${ }^{\boldsymbol{a}}$ A major portion of the income under military contracts is subject to renegotiation. Many contracts are subject to price redetermination. All recent profit statements are therefore tentative only.
    ${ }^{b}$ This figure is based on a change in accounting procedure of one company and therefore not comparable with previous years. If calculated on the same basis as for previous years the figure would be 145.7.
    e This figure is based on a change in the accounting procedure of one company and therefore not comparable with previous years. If calculated on the same basis as for previous years the figure would be 52.7.
    ${ }^{d} 1950$ revised.

    - 1951 revised.

    Source: Aircraft Industries Association, compiled from Moody's Industrial Manuals (1938-1944 editions). Data for 1944 to 1952 taken from individual company reports.

[^33]:    Figures in parentheses indicate loss.
    a Excludes special income credits (portion of reserves for contingencies provided in former years and no longer required).
    ${ }^{b}$ A major portion of the income under military contracts is subject to renegotiation. Many contracts in progress are subject to price redetermination. All profit statements are therefore tentative only.

    Source: Aircraft Industries Association, compiled from Moody's Industrial Manuals (1938-1944 editions). Data for 1944 to 1952 taken from individual company reports.

[^34]:    a First three columns exclude Government-owned assets.
    ${ }^{6}$ Gross property less accrued depreciation.

    - Computed on the same basis as in preceding years.
    ${ }^{d}$ Computed on the basis of a changed accounting practice of one company and therefore not strictly comparable with previous years.
    - Revised.

    Source: Aircraft Industries Assoclation, compiled from Moody's Industrial Manuals (1938-1944 editions). Data for 1944 to 1952 taken from individual company reports.

[^35]:    N. App.-Not Applicable.

    Figures in parentheses indicate loss.
    a On the basis of weighted averages.
    b No allowance is made for stock splits.
    e Excluding special income credits (portions of reserves for contingencies provided in former years and no longer required as reserves).
    ${ }^{d}$ Dividends were paid by only nine of the ten companies which reported net profits. The dividends paid by these companies were only 37 percent of their earnings. The companies reporting losses paid no dividends.

    - Dividends were paid by only 10 of the 11 companies which reported net profits. The dividends paid by these companies were only 50 percent of their earnings.
    $f$ Dividends were paid by only 11 of the 12 companies which reported net profits. The dividends paid by these companies represented 34.6 percent of their earnings.

[^53]:    N.A. Not available.

    - Preliminary.

    Note: The figures shown in this table include all non-certificated carriers, passenger and transport, domestic and international. Several formerly irregular certificated carriers have been granted certificates and have therefore been dropped from this table; this table should therefore not be used to draw conclusions as to trends.

[^77]:    - If companies that failed to supply information are included, the total number of research engineers and scientists is estimated as 94,000 , the total number of research employees as 234,000 .
    ${ }^{\circ}$ Companies were classified by industries according to the largest portion of their total sales. Thus, research personnel engaged in aircraft work in such companies as General Electric Company, Westinghouse Electric Corporation, General Motors Corporation, etc., are not listed under "Aircraft and Parts" but under "Electrical Machinery", "Motor Vehicles", or elsewhere. The number of such personnel engaged in aircraft research is thus undoubtedly greater than here indicated.
