## PREFACE

The United States Aircraft Industry has become what future historians will perhaps consider the most dominant force in the shaping of the nation's economy and security. It has given, and will continue to contribute, in large measures to the freedom and well being of the world.

Today we live in a four-dimensional universe of space and time. Aviation has provided this fourth-dimensional aspect in the annihilation of space and time separating the nations around the earth.

Indeed, aviation has not only revolutionized transportation, but it has forced international isolationism into discard. It has opened new channels of travel and intercourse. It has enhanced the standard of living and the tempo of living.

The development of the airplane has exerted such a profound effect on national and world affairs that only time and the studious analysis of events by historians will enable us to view the first half-century of aviation in its proper perspective.

The time is not far off when any place on this earth can be reached from any other in less than one day. No longer may we consider the North American Continent an island surrounded by friendly nations and ocean barriers. We know, all too well, that the air above us has become an invisible thoroughfare over which not only the peaceful flights of commerce ply, but also supersonic aerial weapons of incredible destruction.

Because of the ever increasing technical advances of aircraft as vehicles of commerce, as well as weapons of defense, public understanding of aviation is of extreme importance.

The contents of this 1955 volume of Aviation Facts and Figures are not works of original research. They represent a compilation of facts gleaned from hundreds of sources in the wor'd of aviation during the past year which have been considered of importance or interest.

It is hoped that this edition may serve as a standard aviation reference work of value to legislators, administrators and managers in government and industry, writers and editors, analysts and students.

President, Aircraft Industries Association D. C. Ramsey, Admiral, USN (Ret.)

April, 1955

The past history of the aircraft industry has been one of dramatic peaks and valleys. Today, coordinated Defense Department long-range planning aims at the maintenance of substan-
tial modern air forces and stable industry production levels.

## PRODUCTION AND FACILITIES

The United States aircraft industry in 1954, was the largest manufacturing employer of all industry in the nation. Today, nearly 800,000 men and women are engaged in producing aircraft-the nation's prime tool of commerce and of defense against aggression.

The military annual purchase of aeronautical products accounts for between 85 and 90 percent of industry's annual volume. Civil aviation production provides a large measure to the productive economy of the nation; indeed, to the world. But commercial aireraft production still represents only a small percentage of the industry's annual output.

Throughout the industry's half century of history the principal difficulties that have beset it have resulted from rapid rises to peak production efforts in wartimes and dramatic production cutbacks in peacetime, Despite the lessons of previous wars-the waste and costliness of rebuilding air power-the industry was all but demobilized and the machinery of research and development of new aviation products virtually halted in early post World War II years.

Between the years 1947 and 1949, despite continual warnings from thoughtful men, there was a steady decline in the total unit output of the aircraft industry. When the Korean War broke with sudden fury in June, 1950, we were caught producing only 215 military aircraft per month-nearly 3,500 aircraft per year less than we were building in 1940 .

In 1950 and 1951 we had practically no jet bombers, and few jet fighters, as against the thousands of jet fighters and bombers of the Communists. As in the past, it was only by herculean efforts on the part of the industry and government that aircraft production was able to step up and meet and beat the Communist threat in Korea.

With the lesson that air power is peace power propounded in World War I, steeped in World War II, and proven a few short years later in Korea, the nation has learned that maintenance of a stable, healthy aircraft industry is the key to the security of America. But only in recent months has the nation and its military forces been able to extricate themselves from the dangerous position of air power low in quantity and quality as a result of post World War II cutbacks.

The modern aircraft, particularly the military weapon, with all its
electronic equipment and arsenal of weapons is the most highly developed instrument of power devised by human ingenuity. The history of the airplane has been one of continuing increases in performance and size, resulting in greater complexity and infinite precision in the manufacturing operation. With each new advance in aeronautical progress new techniques, and methods, and tools, and processes, have been necessary. And usually, this progress can be measured by the necessity for, and intensity of, research and development efforts into completely unexplored fields of human knowledge.

The American aircraft industry has produced more than 521,000 aircraft in its 50 year history. Present production ranges from small 110 mile-per-hour utility planes which cost approximately $\$ 5,000$ to huge supersonic jet bombers costing several million dollars.

## Lead Time for Production

The production of aircraft, following research and development and ultimate decision to produce, involves thousands of inter-related actions and months of time in assembling needed parts, materials and components. Some elements of production time are irreducible; others already have been shortened by the aircraft industry through continuing advances in manufacturing techniques.

This very complexity of the aircraft manufacturing process is, per-
haps, the prime factor in the time consuming operation in the production of an aircraft. This nation's latest heavy jet bomber, for example, upon which the United States Air Force will spearhead its strategic air capability for the next several years, took nine years incubation from drawing board O.K. to first production roll out.

The time factor involved in the production of a modern military warplane, among others, includes: (a) the time required for military experts to establish strategic requirements and to translate these requirements into performance specifications, (b) the time required for design competitions and for contract awards, (c) the time to build experimental models and test them, (d) the time to prepare the production plan-a project that requires knowledge of the production time needed for each of the thousands of parts and materials that go into the finished aircraft (in one giant bomber flying today there are over 184,000 separate parts) and, (e) the time required to test, analyze, and sometimes modify, the first production aircraft.

## Production Facilities

The expansion of the aircraft industry which followed the outbreak of the Korean War, is largely complete. While the 1950 buildup required

E Estimate.
Sources: 2, 4, 14, 76.
The floor space of aircraft industry plants is a rough index of the industry's readiness for emergency production. The post-Korea expansion has ended with floor space at about 75 per cent of the World War II peak.
a broad-scale expansion of aircraft production facilities-land, buildings, machinery and equipment-the job, though difficult, fortunately was made easier because of the immediate experience drawn from World War II, only a decade earlier.

There were considerable facilities still in "stand-by" status dating from the global war. However, a substantial number of these had been made obsolete by technological advances in the physical sciences embraced by the aircraft industry.

Despite the fact that in 1950 we were producing less aireraft per month than we were in 1940, the floor space required for aircraft production in 1950 had increased greatly. In June, 1950, approximately 60 million square feet were being used in the manufacture of aircraft as compared to just under 10 million square feet in 1939.

Overall floor space available for the manufacture of jet fighters, bombers, guided missiles and civilian aireraft of all types, is approximately 127.5 million square feet-about twice that used in 1950.

However, pilotless aircraft and guided missiles as production weapons are just now beginning to join the military services in operational quantities. With the increasingly heavy emphasis laid by the military on these supersonic aerial weapons there will undoubtedly be considerable new facilities construction in widely dispersed areas of the nation for their highly specialized production.

The aircraft industry, in 1954, consumed almost 20 per cent of all aluminum used in metal working industries, It used 2.2 pounds of aluminum, 1.8 pounds of steel alloys, and 4.3 pounds of carbon steel for every pound of airframe weight produced (excluding spares). These figures show the metels consumed not only for the airframe but also for the power plant and for fixed equipment and spare parts. They also take into account the metal that goes into jigs and dies, rejections, scrap and losses in terminated contracts.

Airplanes vary in size from "very small" to "very big." Because of this, industry and government consider airframe weight, rather than aircraft units, to be the best index of production. Military airframe weight production is now leveling off at one-seventh of the World Wor II 1944 peak.

Airframe Weight of U. S. Military Planes, by Type, 1944 and 1954 (Pounds)

Sources: 2, 7.
Because of the ever increasing performance of U.S. aircraft (see p. 42), airframe weights are still on the increase. The average weight per military aircraft produced in 1939, was 4,600 pounds; in 1944, 10,000 pounds; in 1954, 14,300 pounds.

## LABOR

During World War II, more Americans worked to build military aircraft than had been engaged in any other single manufacturing effort in history. Statistically, the industry rose from 41st in rank among U.S. employers to first. By year-end 1943, 1,342,500 men and women were employed directly by aireraft manufacturers, and an additional 650,000 persons were employed by industry sub-contractors and suppliers in the building of the world's most powerful military air force.

Production of this great work force reached its zenith in 1944. During that single year the aircraft industry produced the staggering total of 96,318 aircraft-more planes than had been built in all the world prior to 1940. Military aircraft production peaked in March of that year with 9,113 planes produced and accepted by the military.

Average Weekly Earnings In Aircraft Industry
Weekly earnings of aircraft industry employees are five and a half times what they used to be forty years ago. "Real earnings," which take consumer price changes into account have more than doubled over the same period while hours were cut,

With the defeat of Nazi Germany in May, 1945, and the capitulation of Japan four months later, in September, the dismantling of the world's largest production machine and disintegration of its trained manpower teams began.

By March of 1946, employment in the aircraft industry had dwindled to just slightly more than 219,000 persons.

In 1948, because United States airpower was at a dangerously low level-even for "peacetime operations"-the Congress voted appropriations building toward a 70 -group Air Force and a proportionate buildup of naval aviation.

The size of aircraft industry employee weekly earnings depends upon two factors-the hourly rate and the number of hours worked. Overtime at premium rates pushed earnings up considerably during World War II.

Average hourly earnings of aircraft industry employees have gone up despite the continuous reduction, since 1951, of overtime and overtime premiums. The average hourly rate, excluding overtime premiums in 1954, was about 2 cents lower for the entire industry than the earnings shown here.

By 1950, the uneasy peace between the free world and the Communist Bloc was becoming more restive. Eruption of war in Korea in June, 1950, resulted in a sharp acceleration in preparedness efforts. The Defense Department rapidly increased orders for military aircraft. And, to meet these high demands, the aircraft industry was called upon for the second time in a decade to enter upon a vast manpower program.

Generally speaking, the aircraft industry experienced no severe shortages of production line skills during the Korean buildup-except in a very few areas which had comparatively tight labor situations prior to the war (for example, San Diego, Wichita and Hartford).

The greatest manpower shortages which existed in June, 1950, and which have grown continually more critical since, are in the highly skilled lines : engineers, scientists, technicians and craftsmen. Today, one in 11 aircraft employees is in engineering. The proportion of engineers needed in the aircraft industry grows, as the need for research accelerates and increasingly complex aircraft require greater numbers of engineering man hours.

## EMPLOYMENT IN THE AIRCRAFT INDUSTRY

Sources: 2, 69, 70.
Aircraft industry hiring (Accessions) and Separations have been dropping generally and steadily since 195I, indicating the return to a more normal employment situation. In 1954, for the first time since Korea, separations were greater than accessions. About half of these separations are "quits."

In $1949,47,000$ engineers were graduated from the nation's engineering schools. Since 1950, there has been a steady decline in the numbers of technical graduates from U.S. schools. In June, 1954, the colleges and universities of the United States graduated less than 25,000 engineers and scientists.

In 1954, the average worker in the aircraft industry worked 40.9 hours per week, and his weekly earnings were $\$ 85.02$-about $\$ 3.00$ per week more than his 1952 wage. In most cases, rate of pay is based upon a job classification analysis which sets a rate-range for each of the thousands of different jobs existing in the industry. Employees can advance within the rate-ranges through merit or length of service, or both.

Most aircraft industry employees receive a paid vacation and other fringe benefits, such as seven or eight paid holidays per year, insurance, hospitalization benefits and pension plans.

Most of the aircraft industry is organized by labor. Most workers are affliated with the International Association of Machinists (which entered the aircraft industry in 1934) or the United Automobile Workers (which received a charter covering aircraft workers in 1937).

Women Employees in the Aircraft Industry, 1942 to Date

[^8]Of every 100 aircraft industry employees, 62 work in airframe plants, 21 in engine plants, and 2 in propeller plants. The rest work in plants producing aircraft parts and equipment. World War II and the Korean emergency created a substantial demand for overtime work of aircraft industry employees. Between 1946 and 1950, and since early 1954, weekly hours have been close to the normal 40 hours per week.

## FINANCE

The aircraft manufacturing industry, in financial parlance, is a "contracting industry" and is capitalized accordingly. This requires that the capitalization of companies (1) provide the credit stability and financial strength needed to support a high volume of sales and, yet (2) avoid the costly burden of over-capitalization during the prolonged periods of low volume.

Furthermore, as is the case with other contracting industries, the most economical and efficient method of financing production is for the customer (whether a commercial airline or the U.S. Government) to provide some of the financing needed for performance of the contract. If such were not the practice, and if contracting industries were capitalized to handle their infrequent peak volume, it would be necessary during years of low volume for the price of the end product to include the carrying costs of excess capitalization.

During World War II the customer provided financing in the form of "advances" or contract deposits. During the Korean buildup, customer financing was provided primarily on a "pay-as-you-go" basis of progress payments.

Data contained in the tables in this chapter cover financial activities of the 12 major airframe manufacturers, based upon sales volume for each of the years 1937 through 1954.

## Effect of Emergency Production Expansion on Financial Condition

The degree to which a suddenly expanded military production program affects the financial condition of the industry is shown by the following changes in the financial status of the 12 major airframe companies during the period 1950-1954.

|  | (in Millions of Dollars) |  |
| :---: | :---: | :---: |
|  | 1950 | 1954 |
| Net Worth | \$ 380.0 | \$ 641.5 |
| Working Capital | 287.7 | 442.1 |
| Inventory Net | 208.3 | 592.1 |
| Receivables | 227.4 | 461.9 |
| Plant | 82.8 | 186.4 |
| Sales Volume | 1,388.2 | 4,926.8 |
| Working Capital Turnover (Times) | 4.8 | 11.1 |

Between 1950 and 1954, the total net worth of the 12 companies was increased by $\$ 261.5$ millions, most of which represented reinvested earnings. A major portion of this increased capitalization went into needed production facilities-both brick and mortar, as well as machine tools and equipment.

Working capital in the same period increased $\$ 154.4$ millions. With this expansion of working capital, these companies were able to finance a $\$ 618.3$ million increase in accounts receivable and inventory. To accom-

## PROFIT OR LOSS AFTER TAXES (millions of dollars)

[^9] manufacturers.
plish this financing, working capital turnover was increased from 4.8 times per year to 11.1 times per year.

Because of the nature of the aviation product with its inevitably high unit cost and 16 to 30 month manufacturing cycle, working capital turnover of this magnitude requires careful and close control-both of the amount of the working capital and the manner in which it is used. Under these conditions, the length of time between receipt of cash and its disbursement is extremely short and any disturbance in the flow of incoming cash inevitably has a serious effect upon an individual com-pany's-or an industry's-entire operations.

## Control of Accounts Receivable and Inventories

Control of the manner in which working capital is used requires that constant effort be exerted to keep the amount of funds tied up in accounts receivable and inventories at an absolute minimum and thus to retain in the form of cash sufficient amounts to meet vastly expanded payrolls and to keep on a current basis with mercantile creditors. As an example of the effects of such control, the $\$ 227.4$ million in accounts receivable at the end of 1950 represented an average collection period of 60 days, based upon a sales volume of $\$ 1,388.2$ million; by 1954 , the average collection period for accounts receivable had been reduced to 34 days.

Inventory figures shown in this chapter are net, after deducting progress payments received from the customer during performance of the contracts. The turnover of total gross inventory (not shown in the accompanying tables) was 3.3 times in 1950 at the start of the production buildup, and had slowed to 2.4 times in 1954. In the overall program, however, this inventory turnover has improved considerably. For the year 1955 as the production program continues to level out and deliveries in volume are made to the military ser ices. The inventory picture will improve even more.

## Aircraft Industry Earnings

The earnings of the aircraft industry are subject to a number of profit control measures, including renegotiation, price redetermination clauses, and various types of cost disallowances. During 1954, the average aircraft industry rate of profit to sales of 3.8 per cent was less than the average rate of profit on sales earned by all manufacturers. This comparatively low rate of earnings is not unusual (See Page 31, covering the years 1950 to date). The average earnings for the 12 major
airframe manufacturers from 1950 to 1954 inclusive was 3.1 per cent on sales. During the same period all manufacturing industries reported a return of 6.1 percent.

## MILITARY AVIATION

In 1945, despite hard learned lessons of two world wars, the sinews of United States air power withered. The aircraft industry was all but demobilized, its work forces dissipated, and even the machinery of research and development all but halted.

In 1946, Army and Navy combined were taking delivery of only 139 warplanes of all types per month. The industry suffered great financial loss as it tried to readjust too suddenly to a peacetime economy. It struggled to maintain the huge production facilities left in its charge.

With the demobilization of its men under arms virtually complete, the government turned to the Army Air Forces for the job of policing its far flung outposts-only to learn that this service did not have even one operational group ready to defend the United States. With that blunt truth the machinery of government began to move.

In 1947, the National Security Act gave air power equal status with military surface forces-naval and land forces. On September 18, of that year the United States Air Force was established.

In that year, too, two separate groups were named to study and assist in revising old policies and in framing new ones, and serve as a guide for formulating a carefully considered national air policy. These groups were : The President's Air Policy Comm'ision-composed of outstanding private citizens; and, the Congressional Aviation Policy Board-comprised of members of both houses of the United States Congress.

Both groups dealt at length with related problems that had long plagued the diverse elements in aviation. Aircraft production for the government has always been a stop-and-go proposition. The President's Air Policy Commission pointed out that a series of five-year procurement programs could save up to 20 per cent or 25 per cent in production costs, and recommended such a series. The Congressional Board concurred. Both groups called for the development and construction of early-warning radar networks, a satisfactory airport program, and better naviga-
tional and weather reporting facilities. Together, these reports alerted the public to the abyss into which military aviation had fallen.

Air Power Funds Appropriated, Impounded
In the spring of 1948, the Supplemental National Defense Appropriation Act of 1948 was passed, providing funds to step up aircraft procurement, research, development and operations. The industry received new orders, designed to raise the nation's military air strength, but

## HOW THE MILITARY BUDGET IS MADE

as 1948 rounded into 1949 a sizable proportion of the funds was impounded by Executive action-and many contracts were cancelled.

## The Limited Mobilization

The great debate over air power was resolved less by agreement on principles than by the exigency of war-the North Korean attack across the 38th Parallel. As the buildup got underway under the lash of war in Korea, the military forces and the aircraft industry faced a multitude of problems that had not existed a decade earlier. The developments that grew out of World War II, and reached maturity in the years just after it, had to do with atomic energy, jet and rocket propulsion, guided missiles and electronics. As continuing advances were made in solving these new aeronautical problems, it became apparent that air arms capable of stopping attacks and delivering $A$ - and H -bombs to the heart of the enemy must be maintained in America so long as the threat of war exists.

During 1956, the initial equipping of the 137 -wing Air Force will be practically completed and thereafter production will level off at the rate needed to sustain and keep modern this force and its naval air equivalent. To sustain a 137 -wing force of modern planes-aircraft far more complicated and expensive than pre-Korea models will require an annual investment in new aircraft comparable to the entire Air Force budget of 1950.

## Budgeting for Military Air Power

The determination of the size of each fiscal year's appropriations, and of the manner in which these funds will be spent, is a time-consuming and complicated process.

The roles, missions and responsibilities of the military services result from studies of the Joint Chiefs of Staff, following which the individual services determine the number of planes, airfields, personnel and other equipment required to accomplish these objectives.

With requirements determined, an estimate of financial cost is assigned to each of the force levels-and the development of these dollar amounts results in the detailed defense budget.

Months of military hearings, within the Services and the Department of Defense, follow-during which the budget is explained, defended, cut, adjusted, and changed. It is then presented by the President of the United States to the Congress.

At this point, additional hearings begin in Congress before Subcommittees and Committees; Conference Committees compromise differences between House and Senate. Finally, an Appropriations Bill is passed by the Congress. The amount finally appropriated frequently differs substantially from the amounts originally requested by the Services. In

- As of December 31.
${ }^{6}$ As of June 30 from 1935-1939; as of December 31 from 1940 to 1952; as of June 30 from 1953-1955.

Sources: 4, 8, 12, 82, 83.
The present objective for an active aircraft inventory, in combat and supporting units of the Air Force, Navy, and Marine air forces is close to 40,000 . Actual strength was 34,000 on June 30, 1954, and will be 36,000 on June 30, 1956.
such cases, the Services must then re-program to operate within the limitations set by available funds.

With long lead-time items such as military aircraft, it is normal for expenditures to follow obligations by two or three years.

## Organizations of Wings, Air Groups

Air Force: The basic organizational unit of the United States Air Force is the "wing". A wing is comprised of a combat group and necessary administrative and service units. The number of airplanes in a wing depends on its mission; for example, a group of heavy bombers has 30 planes, a medium bomber group has 45 , a light bomber group 48 , a day fighter group 75, an all-weather fighter group 36-75-depending
upon type of plane and operational mission. The USAF also operates separate squadrons for rescue, support and in-flight refueling. Aircraft comprising these squadrons vary from 8 to 25 planes depending upon type of plane and squadron mission.

Navy and Marines: Navy carrier air groups usually are composed of four fighter and one attack squadrons, and another unit is comprised of night fighters, minelaying aircraft, helicopters and other aircraft. Aircraft carriers (CV) have a complement of from 80 to 137 aircraft depending upon the size of the carrier and the type and size of plane carried. Super aircraft carriers of the Forrestal Class ( 60,000 tons) have 117 to 137 aircraft. Large Midway Class (55,000 tons) carriers have from 100 to 137 aircraft while medium size carriers of the Essex Class ( 33,000 tons) have a complement of $80-90$ aircraft. Anti-submarine squadrons attached to light and escort carriers average about 23 aircraft and shore-based patrol squadrons have nine planes each. Marine fighter squadrons are assigned 24 aircraft.

Army: The United States Army currently has approximately 4,000 light liaison and utility airplanes and helicopters for support of its ground units. That number includes some 600 aircraft which are assigned to National Guard activities. During the next two years Army aviation complement will see about a 20 per cent increase in numbers of helipcopters. During the current fiscal year 1955 Army will obligate approximately $\$ 200$ millions for aircraft.

E Estimate.
Sources: $8,29,30,49,82$,
More than one dollar out of every eight spent by the Federal Government is spent for airplanes. Nearly one quarter of the entire defense expenditures is made for the same purpose; this is the highest ratio ever reached and illustrates the increasing importance of air power to the national security.

[^14]The average number of all military personnel in the fiscal year 1955 will be about 3.2 million. Almost two out of every five military personnel are in the Air Force or Naval Aviation.

## GUIDED MISSILES

The use of guided missiles as weapons of war and aids to commerce is not new. The Chinese, inventors of gunpowder, used rockets, and with some success, as weapons of war against the Tartars in the 13th century. The rocket has been used for signal purposes for hundreds of years, in war and in peace.

In the years between World Wars I and II, considerable advance was made, both in the United States and in Europe, in the field of rocketry and guided missiles. But the true value in the development of the unmanned aeronautical product was lost in our haste to develop mancarrying aircraft.

Although "unmanned vehicles" were flown in this country as early as 1918, serious U.S. military emphasis has been focused on their potential use as weapons only since 1945, when in January, the Guided Missiles Committee of the Joint Committee on New Weapons and Equipment of the Joint Chiefs of Staff was established.

During World War II the significance of pilotless aircraft began to be a vital factor in the international Order of Battle. Both sides developed free-flight rockets in the air-to-surface, air-to-air, surface-to-air, and surface-to-surface categories. Similarly, both began application of "guidance systems" to bomb-like and plane-like devices.

Late in World War II, the Nazi-developed hypersonic V-2, with its powerful liquid fuel and oxidant motor, came close to being the decisive weapon that Hitler expected it to be. It rates as one of the greatest technological achievements of the World War II period.

World War II ended with an ominously firm conviction, on the part of nations, that guided missiles would play a most important role in any future conflict. United States research and development into this "new" field during the first few years following World War II was erratic. For one thing, it was beset by the same financial starvation as all other aireraft industry research, development and production. Then, too, it called for research into hitherto largely unknown fields.

The last eight years, in retrospect however, have seen great strides in guided missiles research and development-and in the last two years, of
production. Currently, defense expenditures in research and development activities related to guided missiles have been equalled in magnitude only by research and development of piloted aircraft.

In the fiscal year 1954, the Defense Department obligated \$269,853,375 for research and development of aircraft and $\$ 231,394,133$ for research and development of guided missiles. In the same fiscal year the Defense Department obligated $\$ 503,545,000$ for procurement of guided missiles and during fiscal 1955 will obligate an estimated $\$ 518,445,000$ for this procurement.

The guided missile, regardless of its employment, is an aerial weapon. Responsibility for its development, then, logically has been a charge of the aircraft industry.

Because complete coordination of contributions from greatly diverse fields of technical knowledge was, and is, necessary in the successful design and development of a guided missile, contract for the complete system has nearly always been called for by the cognizant military service. It is here that the "weapons system concept" in aircraft research, development and production probably found its actual beginning.

The guided missile, operationally, is a weapon of great flexibility. Many require little or no especially prepared launching aprons and may be fired from almost any vantage points the using agency could selecton land, at sea, or in the air.

There are five categories of military operations into which the guided missile fits, whether the service is Army, Navy, or Air Force: Air De-

The Air Force has taken the lead in procurement of guided missiles. In 1955, it will spend more money on guided missiles than the Army and Navy together. However, Army procurement is expected to approach Air Force levels again in 1956.

Because of the very rapid growth of the aircraft industry-military missiles program much of the money made available in current and past years has not yet been obligated for specific contracts or, if obligated, is yet unpaid because the contracts are not completed.
fense, Combat Air Support, Land Combat, Sea Combat, and Strategic Offense.

As a team, the aircraft industry, science and government, despite making great strides in the myriad fields of guided missile research, have only scratched the surface of this aeronautical frontier. There are an imposing number of problems, many only partially solved and a great deal more still only theory. Nearly every field of human technical knowledge enters into the research and development and operational applications of the weapon - aerodynamics, thermodynamics, power plants, fuels, combustion, ceramics, meteorology, ballistics, electronics, nuclear physics, servos and control equipment, launching methods, guidance systems, and thousands of others.

## Guidance Systems

The guided missile is, in light of other expendable weapons, very expensive. Measured in terms of "hits," the cost factor is largely academic. In terms of a "miss" it represents substantial loss. Probably the most expensive item in the fabrication of the weapon is its guidance system. Considering the fact that the value of the weapon, in final analysis, can only be measured in terms of its accuracy, guidance systems have become the object of most of the intensive research.

Guidance methods, under development and in operational use, are of two general categories-electronic and non-electronic. The non-elec-
tronic systems are, of course, far less susceptible to enemy intercept countermeasures. This type of guidance system falls into two general categories-celestial and inertial. Guidance systems of this type generally make use of several gyroscopes. As with the simple gyroscopes that may be purchased in any toy store, in physical operation, a guid-

## E Estimate.

Source: 49.
In the five fiscal years, 1951 through 1955, approximately 1.6 billion dollars have been provided for research and development of guided missiles systems. Such funds now almost equal research and development funds for aircraft.
ance system gyroscope maintains a constant orientation on its axis in three-dimensional space. This factor in guidance provides a reference system for guidance, and is the basis of the "inertial" system.

The system of devices enabling guidance to be controlled by automatic star tracking, eliminates any interference from surface countermeasures and is called "celestial."

The most obvious type of electronic guidance is "radar homing" on an enemy target. There are three primary types of this system. "Active" homing is accomplished by the missile's radar antennae which continually indicates the target. "Semi active" homing is accomplished by a surface or airborne radar separate from the missile and transmitting guidance instructions. "Passive homing" is accomplished by letting the missile home on any pre-selected electrical device that the enemy target may be operating.

Another type of guidance is the "command" system. This is a system involving both radar and radio. In one type, ground radars are pointed at the missile and at the target. A computer receives electrical information from the radars and transmits guidance to the missile. In another, the computer is built into the missile and radio contact between ground and missile is eliminated.

## Power Plants

Of extreme importance to the guided missile is the ability to preclude interception. In addition to the need for the missile's guidance system being capable of ignoring enemy countermeasures, speed is one of the surest ways to elude enemy interception.

While guided missile power plants today are of two general typesthose requiring atmosphere in which to operate and those which do notboth are actually "rocket-like" in propulsive power. Both develop their forward drive from fuel, oxygen and ignition. The reaction of the expanding gasses as they escape through the rear of the engine provides the thrust power.

Guided missile engines used in today's operational weapons are generally satisfactory in relation to the overall state of guided missile art. However, one of the greatest problems confronting industry is efficient fuel utilization. The missile engine, whether it be jet or rocket, consumes tremendous quantities of fuel. As a result much research effort is placed in the development of new fuels and in the refinement of present fuels.

So far, the two principle types of engines-jet and rocket-are about equal in power plant application. Each have unique advantages not found in the other. The day will undoubtedly come when atomic energy will provide the motive power for either un-manned or manned ballistic

## AIRLINES AND TRANSPORTATION

The United States airlines, on scheduled domestic and international routes, during 1954, flew a total of $34,131,000$ passengers $20,411,884,000$ passenger miles.

The airlines, in addition to establishing this all-time record of passengers carried, also proved that they are one of the safest means of transportation in the world. Between January 1954 and December 31, of that year they suffered only 16 passenger fatalities. This is the equivalent of flying 1.3 billion passenger miles for each passenger fatality.

The railroads, on the other hand, although they traveled considerably more passenger miles ( $29,270,000,000$ )-particularly with very short haul commuter travel-suffered 21 passenger fatalities, and recorded a .07 fatality rate per 100 million passenger miles against the airlines .08 fatality rate per 100 million passenger miles.

In 1954, the domestic scheduled airlines flew $16,700,000,000$ pas-

senger miles, while comparable railroad pullman travel amounted to only $7,300,000,000$ passenger miles. In that same year, more than 60 per cent of all persons entering or departing from the United States traveled by airlines. United States international airlines carried 1,714,618 passengers and ocean voyaging steamships carried $1,112,117$ passengers.

Already, the domestic airlines carry more passenger-miles of revenue traffic than the railroads comparable "pullman car." They also surpass railroad passenger traffic by "coach" (except commutation).

## Speed and Cost

Wagon transport on the Philadelphia-Lancaster Turnpike (which was finished in 1794) moved at a snail's pace and at a cost of 13.5 cents per

U.S. airlines have the smallest employment but the highest earnings per employee in the transportation system. The figures shown do not include government and industry employees and independent operators who build and maintain highways, operate service stations, maintain airways, etc.
ton-mile. Today, with a much cheaper dollar, railroad freight moves for about one and one-half cents per ton-mile and travels a few hundred miles per day, while air freight crosses the continent in less than a day's time for about 20 cents per ton-mile.

A passenger who took the stagecoach from Pittsburgh to Philadelphia in 1812 had to spend six days on the road and paid 27 dollars for the trip. In 1834 he could cover the distance by rail, canal and stagecoach in less than four days for about $\$ 15$. Today, when the dollar is worth much less, the fastest train will take him there in six hours for $\$ 11.81$ by coach, or $\$ 18.25$ by parlor car. If he takes a plane he can make the trip in one hour for $\$ 16.75$.

## Government Experiments with All First Class Mail by Air

Since October of 1953, the scheduled airlines have been conducting an experiment for the Post Office Department which is bringing improved service to the public and at the same time reducing the Department deficit. The airlines are carrying first class mail by air on several routes -at first class postal rates-when air movement will give the fastest service.

For example, the airline run between New York and Chicago alone is realizing revenues for the Post Office Department of more than $\$ 2,000$ per ton of mail flown. One ton of mail moved between the two points brings a gross revenue of $\$ 2,314.00$ to the Department. Of that amount $\$ 134.66$ is paid to the airlines; the balance, 94.2 per cent, is retained by the Post Office to pay for its operating ground expenses.

## Military Air Travel

The Defense Department, responsible for the mass movement of personnel, is probably more conscious of efficiency and economy than any

Travel becomes faster, more convenient and, frequently, less costly. With travel over long distances, the savings in time and travel expense for food and accommodations possible through air travel become more important. Cheaper air tourist fares are available.
other "business" in the world. Prior to 1949 , only two percent of the military establishment's official group movements of 15 or more individuals traveled by air. Today, more than half of all military group movements, in that quantity, are made by the airlines.

For example, in 1953, the scheduled airlines handled more than 818,000 military passengers. The fast movement of these officers and men saved the government $22,054,325$ man hours, representing a manpower saving of approximately 8,797 men working 48 hours per week for an entire year. This is the equivalent to the productive time of more than one-half of an Army division. In terms of the base pay of an Army private, in productive time alone, the savings to the military would amount to $\$ 2,407,000$.

The largest scheduled airline movement of military personnel to date involved over 3,000 men. Transcontinental air movements of 650 or more men are routine to the scheduled airlines.

| 1954 | 274,001 | 155,755 | 118,246 | 379,119 |

- Figures for eastbound passengers not available until 1950.

Source: 65.

Airlines carry more than two of every five passengers across the Atlantic and Westbound traffic remains heavier because of continued immigration. Foreign airlines are increasing their share of total passenger traffic.

## Costs Rise, Fares Drop

Despite the spiraling upward costs of operation, travel fares continue to decrease. In 1937, a scheduled airline passenger traveled at 5.6 cents per passenger mile; now he can travel by air coach at 4.26 cents per passenger mile. This saving to the traveling American public has been achieved despite a 90 per cent increase in the general consumer price level since then. In addition, the vast improvement of service, comfort and safety is virtually incomparable.

- Less than one-half million.

Source: 37.
During the last six years the activities of the major air carriers have grown at a very rapid rate. Passenger traffic increased almost three fold, cargo-miles more than tripled, and mail ton-miles doubled.

Average Passenger Loads, 1939-1953
(Passenger-Miles per Vehicle-Mile)

| Year | RR <br> Coaches | Sleeping <br> \& Parlor <br> Cars | All RR <br> Passenger <br> Cars | Class I <br> Inter-City <br> Busses | Scheduled <br> Domestic <br> Airliners |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 1939 | 17.0 | 9.3 | 13.4 | 16.4 | 7.9 |
| 1944 | 41.0 | 20.3 | 31.9 | 24.9 | 15.2 |
| 1949 | 23.6 | 11.0 | 18.1 | 18.4 | 19.2 |
| $1953^{\mathbb{E}}$ | 23.9 | 10.2 | 17.8 | 18.7 | 29.2 |

[^20]On an average trip, an airliner carries more passengers than any other vehicle-almost thirty. This compares with only ten for the average Pullman Parlor Car or Sleeper, and 24 for railroad coaches.
U. S. Scheduled Airlines-Aircraft in Service by Make and Model 1941-1954

[^21]Five airplane and two helicopter aircraft manufacturers in the United States supply all the airline aircraft now in domestic or U.S. international service. These aircraft represent a value (after depreciation) of about $\mathbf{5 0 0}$ million dollars.

## E Estimate.

Sources: 2, 38.
The scheduled airlines now offer service at rates which vary from slightly more than 4 cents per mile for coach to about six cents per mile for first class service. Non-scheduled airlines fares vary considerably, but their average is slightly more than 3 cents per mile.

## Source: 79.

1954 data for scheduled U.S. airlines show that the domestic and international airlines carried $34,000,000$ passengers almost 20.5 billion passenger miles. During the 12 month period there were only 16 passenger fatalities. This all-time best safety record brings the fatality rate to an all-time low of .08 per million passenger miles flown.

Despite the enormous increase in carrying capacity of U.S. airlines almost two out of three plane seats are filled. While this is a substantial improvement over-pre-war figures, it is below the very high percentage of seats filled during the war. Passenger seat-miles flown will increase sharply as the airlines, now actually "long-distance" carriers, begin to capture the "short-distance" commuter market. So far, this potential is largely untouched.

As might be expected, the average length of trip in international service is much greater than in domestic. U.S. international airlines in 1954, flew nearly 3 million passengers without a single fatality.

In 1932, the domestic airlines had only 2,000 seats available; by 1941 these had grown to 6,500 , by 1946 to 24,000 . Today there are 60,000 . The increase in average speed makes this growth of carrying capacity even more impressive.

Although airmail carried by U.S. airlines is increasing rapidly, it provides a much smaller share of airline income today than it did in the earlier days of airline operation. Even conventional first class mail now often goes by plane.

The domestic airlines of the United States employ nearly seven pilots and co-pilots per plane, and about nine other employees for every flying officer-a total of 71 employees per plane. U.S. international airlines employ nearly 11 pilots and co-pilots per plane and 155 employees per plane.

## GENERAL UTILITY AVIATION

Air transportation is not confined just to the airlines. Private aircraft are playing an ever-growing role and are being extensively used in various fields of business, industry and agriculture.

Civil aviation divides generally into two segments, more popularly called Airline and General or Utility Aviation.

The airlines utilize the larger multi-engine aircraft along with helicopters and a few single engined aircraft for specialized local service activities in carrier aviation. General aviation utilizes all types, but principally light transports, some helicopters, and large numbers of single engined aircraft.

There are four principal types of utility aircraft:

1. One- to two-place, having a gross weight of 1,500 pounds or less. Powered with 65 to 150 horsepower engines, they have speeds from 70 to 125 miles an hour. In this group are found the sort of aircraft most often used for instruction, for light agricultural use, and for sport flying.
2. Three- to four-place, weighing from 2,200 to 2,700 pounds and powered with engines from 125 to 225 horsepower. These are good "cross-country" aircraft, able to maintain cruising speeds of $125-175$ miles per hour, and have endurance of three to four hours without refueling.
3. Four- to five-place, having a gross weight of from 2,200 to 4,600 pounds and powered with engines from 175 to 300 horsepower. These planes can cruise 140 to 225 miles per hour and are generally referred to as executive aircraft. They are well equipped with radio and instruments, and capable of cross-country flight under instrument conditions.
4. Four- to ten-place, twin-engine light transport, with 175 to 500 horsepower engines. These aircraft, in demand by corporate users, have a cross-country speed of from 150 to 225 miles per hour; four to seven hours endurance, and extensive instrumentation and radio enable these aircraft to operate in marginal weather-much as do the scheduled airliners.

In addition to these four principal aircraft types, there is an active fleet of several hundred larger multi-engined aircraft, identical to planes

## HOW UTILITY AIRCRAFT ARE USED

BUSINESS uses aircraft as the best means of rapid, safe, and economical transportation of executives. Often these planes are owned and operated by businessmen themselves. Fleets are frequently maintained by corporations who retain professional pilots to operate these aircraft. 35,070 utility aircraft are operated by the nation's businesses, corporations and partnerships. Of these, 18,220 are company owned.

AGRICULTURAL applications of utility aircratt ore increasing. Today, one of every 12 acres under cultivation in the United States is either sprayed or dusted by aircraft.

INDUSTRY, always conscious of time and cost, has developed the airplane into one of its prime tools. From uranium prospecting to the fast delivery of heavy equipment, 2,520 aircraft are hard of work for industry.

PERSONAL aircraft to air traveling America, has taken on characteristics of the "private automobile". There are 29,260 utility aircraft of all sizes and types used today for both business and pleasure transportation.
used by the airlines, in use by corporations for business purposes, principally executive transportation.

The use of aircraft in business has shown steady acceleration in recent years. Civil Aeronauties Administration statistical data emphasize this fact. According to CAA, business uses of aircraft accounted for 2.6 million hours in 1949. The CAA estimate for 1954 credits business aircraft use with 3.9 million hours, a 50 per cent increase over 1949.

During 1954 the airlines of the nation, based on an analysis of Air Transport Association data, flew an estimated 3.1 million revenue hours, 810,000 less hours than in business aviation. The business fleet now includes more than 20,000 active aircraft, the scheduled airline fleet is less than 1500 .

## Civil Aircraft by Year of Manufacture

As of January 1, 1953

| Year <br> of <br> Manufacture | Number | Percent of Total |
| :---: | :---: | :---: |
|  | 89,313 | 100.0 |
| 1942 | 6,567 | 7.3 |
| 1943 | 4,741 | 5.3 |
| 1944 | 6,254 | 7.0 |
| 1945 | 1,591 | 1.8 |
|  | 1,940 | 2.2 |
| 1946 |  |  |
| 1947 | 27,521 | 30.8 |
| 1948 | 11,325 | 12.7 |
| 1949 | 5,569 | 6.2 |
| 1950 | 2,767 | 3.1 |
|  | 2,973 | 3.3 |
| 1951 |  | 2.2 |
| 1952 | 1,930 | 3.2 |
| Other years | 2,847 | 14.9 |

Source: 33.
This table shows that only about 10 per cent of all utility planes are less than four years old. About half of all passenger automobiles are in that recent age group.

## Development of General Aviation

There was little flying during the '20s and '30s which could be called utility or general aviation in today's use of those terms. Commercial and business aviation in that period was related to the early growth of the airlines and to servicing the small fleet of privately owned aircraft. In 1940, just before the start of the second World War, there were
several thousand light aircraft of a type which could be used for corporate and other utility purposes. But, by and large, such flying as privately done was mostly for personal pleasure or sport.

Prior to the second World War the Federal government established the Civilian Pilot Training Program (CPTP). It was designed to increase the knowledge of aviation and to build a reserve of trained pilots

## Estimated Cost of Operating a Typioal 125 Horsepower Utility Airgraft Seating Four People

## Direct Costs per Hour

Gas and oil ..... \$2.70
Inspection and maintenance ..... 65
Engine overhaul ..... 82
Hourly direct operating cost ..... \$4.17
Indirect Costs per Year
Hangar ..... \$ 240.00
Insurance ..... 474.99
Depreciation ..... 1,548.75
Annual Fixed Cost ..... \$2,263.74

|  | 300 Hours | 500 Hours | 1000 Hours |
| :---: | :---: | :---: | :---: |
| Total cost per hour | \$11.72 | \$8.70 | \$6.43 |
| Cost per passenger seat mile | 2.33¢ | $1.73 \phi$ | 1.27¢ |
| Cost per mile at 125 mph | 9.3 ¢ | 6.9 ¢ | 5.1 ¢ |

Source: 87.
Operating costs of small executive planes approach the operating cost of automobiles, provided the plane is used an average of one hour a day or more.

E Estimate.
Sources: 32, 35.
Since 1952, the number of active aircraft has beon increasing. Many surplus and training planes of the 1940's are still in existence but inactive.
for the military. The demand for small trainers caused by this program resulted in a pre-war manufacturing spurt.

The start of World War II, however, forced a shutdown in the manufacture of light civil aircraft. The CPTP program was halted and replaced with one designed more specifically for wartime needs, known as the War Training Service (WTS). From this developed the wartime contract training of military aviation personnel conducted so successfully during the war years.

Though civil manufacture was halted, almost every type of light aircraft then being produced found some wartime use. Also, about 2,000 light aircraft were taken over by the military for instrument and other training purposes, and for use as light utility cargo and personnel transports.

The Army subsequently acquired and used many thousands of light aircraft for liaison purposes. Used first as artillery spotters, they soon demonstrated a multiplicity of uses. Their versatility is best described by the term then so frequently applied to these small aircraft-"flying jeeps." These military uses of light liaison aircraft dramatically demonstrated the everyday utility available in typical light aircraft.

There was a steady decline in numbers of light aircraft produced since 1946 when nearly 35,000 were produced in comparison to 1951 when only about 2,300 were delivered. However, aircraft produced in the early post-war years were light trainer types, unsuited for business or even for personal use. This resulted from the G. I. Bill of Rights which caused a great post-war training boom with many thousands of veterans taking flight training. As a result, the base operators who did the G. I. training, were the industry's biggest customer, not the individual aireraft owner or user.

It wasn't until 1947 that a sound and steady growth in the acceptance of general utility airplanes in business began. Since 1947, there has been a steady growth in the utility aircraft industry. Three principal factors account for this: 1 . Demonstration of worth of the utility airplane as a profitable business tool; 2. the great improvement in the aircraft itself; and 3. the user's ability to obtain greater utilization out of the airplane.

## Mobilization of General Aviation for Civil Defense

There are plans in existence today which, under conditions of military emergency, would make several hundred transport aircraft quickly available for purposes of military air-lift. These plans have been jointly worked out by the Commerce Department's Defense Air Transportation Administration, Department of Defense, and the nation's airlines. An
emergency would invoke the activation of these plans and would also intensify the need for civil air transportation generally, for essential business, industry, agriculture, and for civil defense.

The CAA estimates that, among the general aviation fleet, there are more than 20,000 aircraft which are considered to be in daily use for business purposes. Of these, at least 15,000 are four-place aircraft of a type especially suitable for executive transportation. This group of

Source: 32.
While there is about one motor vehicle for every three people in this country, there is only one active airplane for about every 3,000 persons. On a per capita basis, plane ownership is highest West of the Mississippi.
aircraft is capable of providing as many as $10,000,000$ seat miles of transportation an hour. There are, of course, many thousands of other aircraft in daily use, including approximately 2500 multi-engined aircraft, more than are operated by the airline industry.

Apart from the daily use of the general aviation fleet in routine business, industry, and agriculture, this fleet of thousands of light aircraft provides a reserve of transportation which could be vital. Under the conditions which would result from atom bombing, it is reasonable to assume that the usual surface transportation would be either at a standstill or badly disrupted for many hours following such an attack. But the air-lanes would still be open. Light aircraft capable of landing in small areas under emergency conditions could become the chief link between life and death, bringing the supplies and providing the communications necessary to re-establish devastated areas.

[^25]Pilot certificates, once issued, remain in force permanently. However, to hold an active "ticket," periodic physical examinations are required. A survey of active pilots on January 1, 1954, showed 11,419 active transport pilots, 67,809 active commercial pilots and 153,426 active private pilots, or a total of only 232,654 instead of the 585,974 shown for the same period who "hold" certificates.

Federal airways are "highways in the air" ten miles wide and divided into several traffic levels a thousand feet above each other. Traffic is guided and controlled by radio signals, beacon lights, weather reports, instrument approach systems, radar facilities, traffic control centers and towers. The tables show the growth of this system.

| Region | Total | Airports by Length of Runway (in feet) |  |  |  |  |  |  |

The airports shown in this table receive scheduled air carrier service or offer minimum public service of full-time attendant and fuel sale. In addition to these public airports there were 3,857 "limited" airports making a total of 6,760 airports. More than 1,000 fields were lighted for night flying.

## HELICOPTERS

Five hundred years ago, Leonard da Vinci sketched plans for an aerial screw design for vertical flight. The helicopter, ${ }^{*}$ as we know it today, derives lift from an overhead rotor, or rotors (the large screwthread on a vertical shaft theory of da Vinci).

Since da Vinci's time more than 100 different helicopters were designed and built for attempted flight, but it was not until the advent of the gasoline engine that much progress was achieved.

In 1907, Louis Breguet in France flew a helicopter that weighed half a ton and was driven by four rotors. In the ' 20 's, Juan de la Cierva in Spain experimented with rotary wing flight (non-powered autogiro rotor principle.) His development of the hinged rotor blades, rather than the rigid type, proved an impotrant contribution to the design of practical helicopters. The first real distance flight by helicopter was made by Dr. Heinrich Focke from Bremen to Berlin in 1937.

In 1939, the first successful helicopter flight in the Western hemisphere was made by Dr. Igor Sikorsky at Bridgeport, Connecticut.

During World War II, the Army, Navy and Coast Guard began limited use of helicopters in military combat operations. In this period, however, their use was restricted almost completely to light emergency transport and rescue.

Introduction of atomic weaponry by the close of World War II, as with other military tacties, forced a radical change in techniques of assault landings. The helicopter offered the third dimension-vertical landings-to the aspect of amphibious and air-head assault.

Prior to, and during, the late global war, development and production of the helicopter was, for the most part, experimental and limited. It wasn't until March 8, 1946, that the first commercial helicopter was certificated by the Civil Aeronautics Administration.

[^27]Early in 1947, the Marine Corps formed the first experimental helicopter squadron to test proposed combat techniques. The Coast Guard had already pioneered in proving utility of the helicopter as a rescue vehicle and a year later it became an integral unit in air rescue operations of the Air Force.

Today, less than 10 years later, helicopter manufacturing employment has risen to approximately 15,000 . The industry as of December 31,1954 , had an estimated backlog of 550 million dollars. Sales in 1954 totaled more than 155 million dollars.

The Korean war brought into sharp focus the unique utility of the helicopter in military operations and the great potential of the helicopter

to civil aviation. Aside from its capability as a rescue vehicle, the 'copter proved outstanding for aerial survey, flying food, medicine and ammunition over difficult terrain to supply front line posts and for quick transport of personnel to strategic points. The helicopter also was credited with the rescue and evacuation of more than 23,000 United Nations personnel including pilots who were shot down behind enemy lines, as well as evacuation of front line casualties. Many of these missions were performed at night in inclement weather.

In 1947, the world's first scheduled helicopter mail route was established to serve a 50 -mile radius of Los Angeles. Two years later, the Civil Aeronautics Administration authorized similar service for the Chicago area and in 1952 in the New York area.

In July 1953, the first scheduled helicopter passenger, mail and cargo service was established in New York and another now is authorized in

Los Angeles. Today, helicopter service is also available between airports and airports and city in Pittsburgh and Cleveland, and this year will be inaugurated in Indianapolis. In 1953, two U.S. scheduled airlines inaugurated helicopter passenger service. In Europe, Belgium inaugurated the first international helicopter passenger service in 1953 between Belgium, the Netherlands, France and Germany.

The New York Police and The Port of New York Authority use the helicopter in solution of official transportation problems. Operating off waterfront, roof-top and airport heliports, the police use small helicopters for quick transport of key personnel over traffic-congested Manhattan.

In agricultural operations the helicopter has established an enviable record : crop dusting, spraying, aerial and geological survey, mapping, power line patrol, off-shore drilling service, uranium prospecting, and frost control are only a few of the services offered by some $25-30$ commercial fleet helicopter operators. Large ranchers find the helicopter invaluable in ranch activities. For example, the huge Waggoner Ranch, covering more than 500,000 acres in Texas, find the helicopter equal to $15-20$ cowboys in rounding up cattle and in the patrol of 2,700 miles of fence lines.

The short-haul travel market-up to 300 miles-is a comparatively untapped potential helicopter air travel market. Present day ground travel time from the airport to the city business district is often as long as the air trip itself.

Full utilization of the helicopter as a short-haul, city-center to citycenter transport is only limited by the lack of "downtown" heliports. In this connection, the Helicopter Council of the Aircraft Industries Association has recently completed a survey of the nation's state aviation
laws. In most cases, according to this analysis, the helicopter is handicapped by being classed in the general "aircraft" category, without recognition of its operational capabilities. The Council, working with the National Association of State Aviation Officials, will seek a remedy for this unsatisfactory situation.

Today, nine major helicopter manufacturers are producing or are engaged in experimental development projects for the military. These rotary winged craft include: small $2-3$ place models for training, rescue and observation; light transport models seating 10-16 passengers, and larger types which will seat from 40-50 passengers.

There are 11 models in production, 14 in prototype and 9 models in the design-development stage, including very large versions to serve as "flying cranes"-for the military, in transporting mortars and bridge sections over rivers and mountains and in civil use, for construction companies-by moving heavy equipment and machinery to and from building sites anywhere.

## AIRCRAFT EXPORTS

American businessmen go almost everywhere in the free world to sell American products and, because of the speed and economy of air travel, export business has become almost as routine as the pursuit of domestic sales.

The greatest problem in doing export business, however, has not progressed so rapidly. The world is faced with exchange restrictions, quotas, tariffs, and other limitations which still make it much more difficult to do export business than domestic.

Although the airplane is responsible for easy access to world markets, products of the aircraft industry suffer the same handicap as all other merchandise when it comes to changes in national ownership. While the attitude of those behind the iron curtain is largely responsible for the restrictions existing even between friendly countries, the tremendous improvement and growth of military, as well as civilian, aircraft products is largely due to military protective incentive and cooperative agreement of the free world.

Aircraft production in the United States exceeds that in all the rest of the world with the exception of Russia. Russian production, of course, is a matter of speculation. Some quarters feel that Russia is producing more than the United States, and others, that she produces considerably less.

Because of the restive international situation, however, public information regarding the manufacture and export of aircraft, engines and components has been so restricted that detailed statistics cannot be compiled. Overall U.S. dollar exports increased annually following World War II from 1946 to 1954 with reversals only in 1948 and 1954. The overall aircraft industry product export for the past three years has been as follows:

| 1952 | \$603,000,000 |
| :---: | :---: |
| 1953 | 880,000,000 |
| 1954 | 619,000,000 |

No details of U.S. exports have been available since 1949 with respect to military aircraft types, quantity, or destination. A considerable
part of the more important civilian items of complete aircraft and parts have similarly been restricted.

The destruction of the German and Japanese aviation industry was complete in World War II. During the last year both nations have been accepted as "members in good standing" by the free world. Both, in pre-war years, were formidable competitors in world export markets. Both, with assistance of the United States, are making rapid progress in the restoration of their aircraft industry. Neither, however, will be able for some years to offer competition to the United States in world exports.

Much of the aircraft industry of France, the Netherlands, Belgium and Italy was destroyed during World War II. The United States

NEARLY ONE-TWELFTH" OF ALL AIRCRAFT PRODUCTS ARE EXPORTED

through several aid plans-the foremost being the Mutual Defense Assistance Program-has done much to refurbish the industry of those nations, including substantial "off-shore" procurement of military aircraft, engines, electronics, etc., for use by the free world.

While off-shore procurement has done mrch to restore the industry of those nations and has greatly strengthened the military posture of allied air forces quantitatively, none has been able to match the qualitative definition "Made-in-America," as applied to the aviation product. Great Britain

Since World War II, Great Britain, Canada, and France have all made great strides in the export of aviation products-particularly in military items. Great Britain, in addition to making considerable progress in the export of military aviation end items, has also placed heavy emphasis on the export of civil aviation products.

While ill fate has followed the production of the British jet-powered DeHavilland Comet, nevertheless the British have made substantial progress in the redevelopment and production of this aircraft. The turboprop Vickers Viscount, medium transport type, has, on the other hand, distinguished itself and is becoming a substantial import into the United States. Their larger turbo-prop aircraft, the Bristol Britannia, shows promise but is not a substantial production item as yet. However, it remains to be seen whether the largest jet type transport aircraft still will not be supplied primarily from the United States. Turboprop development in the United States is moving rapidly.

## Utility Aircraft

The United States has always excelled in the number and quality of utility aircraft supplied both at home and for export. In recent years $15-20 \%$ of all such production in the United States has been exported. While Great Britain and France have supplied much of their demands at home, they have done very little exporting of this type of aircraft.

## Canada

Canada has worked in close cooperation with both Great Britain and the United States in her production of a very substantial volume of aircraft. She has combined the airframes of the United States with power plants from Great Britain and vice versa. In addition, she has designed and produced numerous airframes and power plants in her own companies. She has supplied substantial quantities of trainers, fighters and bombers for Europe and elsewhere, and has sold some of her liaison type aircraft in the United States, despite domestic competition.

United Kingdom: Aeronautio Exports

| Annual <br> Average | Million <br> Dollars | Annual | Million <br> Dollars |
| :---: | :---: | :---: | ---: |
| $1924-1928$ | $\$ 5.6$ | 1949 | $\$ 125.2$ |
| $1929-1933$ | 7.1 | 1950 | 95.2 |
| $1934-1938$ | 16.3 | 1951 | 116.5 |
| $1939-1943$ | 33.9 | 1952 | 121.6 |
| $1944-1948$ | 57.7 | 1953 | 182.0 |
|  |  | $1954^{\mathrm{E}}$ | 156.9 |

E Estimate.
Sources: 11, 56.
Exports have been much more important to the British aircraft industry than to the American. About one quarter of total British production is exported-compared to about 10 per cent of U.S. production.

United Kingdom: Employment and P duction in the Aircraft Manufacturing Industry

| Year | Employment | Value of <br> Production <br> (Million Dollars) |

Exports of large air transports in 1954 have reached an all-time high both in number and in dollar value. This indicates that the United States will maintain its leadership as the major supplier of planes for the world's airlines.

## TRAINING

In the final analysis the quality of the U.S. aviation product, whether aircraft, engines, components, electronic devices, etc., is determined by the men and women that design, build or fly.
U.S. aviation leadership is the product of thousands of men and women who push back the frontiers of knowledge, and who apply what has been learned to the design and production of more advanced aircraft for civil use, and planes, guided missiles and electronic devices for the military.

There are engineers, draftsmen and production line workers. There are skilled technicians who maintain and direct air traffic. There are highly skilled crews who fly the nation's commercial and military aircraft. There are managers in the aircraft and air transport industries, in the military, and in the civil services of government who plan and guide America's gigantic aviation effort.

The lowest common denominator of American aerial supremacy is training and education-in manufacturing, in maintenance, in the military and in civil aviation.

Examination of any big city newspaper will disclose great numbers of opportunities in all aspects of the aircraft industry for pilots, for engineers, for research specialists, electronic experts, and for production workers.

The aircraft manufacturing industry, which has been repeatedly faced with shortages of skilled personnel, undertakes apprentice and in-plant training programs. Some of the larger companies offer advanced courses in various technical aspects of aviation research, development, and production. These companies, hard pressed for qualified technical personnel in most cases, will take qualified engineers in any field and train them to their aeronautical need.

The nation's airlines operate flight and ground schools for the orientation and training of new employees, and for maintaining a high level of personnel efficiency.

The high schools and colleges of the nation, more and more, are
increasing their curricula to cover many fields of aviation. Colleges are, in many cases, offering pre-flight aviation training, and some offer flight training. Texas A \& M College, for example, with the assistance of the Civil Aeronauties Administration is establishing a special six-weeks flight training school to train pilots in "aerial applicator" flight. This particular adjunct of agriculture is assuming tremendous proportions as America strives to increase her productivity to meet domestic and international food needs.

During World War II, more than 160 civilian aviation schools were under Army Air Force contract to train flying and technical personnel. To a lesser degree, the Air Force employed this system of contracting with civilian schools during the early days of the Korean War.

The Air Force has since discontinued its use of civilian schools for other than primary flying instruction, and as a result most training schools have been faced with serious economic problems during the last eighteen months. The picture is brightening generally, however, as the

The attrition in numbers of flying schools is continuing. However, student pilot licenses have reversed their long downward trend and beginning to increase. The military services train their own pilots-the USAF about 7,800-Navy about 2,000 aviation cadets per year.
significance of the civil aviation industry to the nation's economy in peacetime emerges.

In 1950, pilots were being trained for the Air Force at an annual rate of 3,000 . With the advent of the Korean War, this rate was increased to 4,000 per year, then to 7,200 per year. Pilot output during 1951 through 1953 remained at approximately 7,200 per year. In 1954, however, Air Force pilot output once again began to drop. In fiscal 1955 (July 1954-July 1955) pilot output is pegged at approximately 6,000 annually.

The number of new pilot licenses issued annually in the U.S. is reversing the past decline and is now increasing in all categories.

## RESEARCH AND DEVELOPMENT

The military aerial weapons user is never satisfied. If he were, he would soon be outdone by his adversary. Yet, aircraft industry production lines require stability if the nation is to have air forces and air power "in being."

At the same time, however, of prime concern to the nation is the maintenance of an air power second to none whether the weapons be piloted aircraft or unmanned guided missiles. As a result, the balance of dollars and effort between production and inventory on the one hand and research and development on the other is difficult to determine for both industry and government.

Following World War II, research and development conducted by the aircraft industry was virtually smothered in a landslide of cancelled contracts and heavy slashes in the defense budget.

As a result, the Korean War found this nation with practically no jet bombers and relatively few jet fighters. The thousands of aircraft built for the Air Force and Navy, during and after the Korean build-up, were far more expensive than they needed to be for the industry was not prepared to build them under emergency schedules and its research and development nucleus was just beginning to gather personnel in strength.

Today, with the nation's air power goal in sight in terms of numbers, an increasingly heavy emphasis is becoming evident in the research and development of higher performing aircraft, engines and guided missiles and their components. The industry, geared for the "long pull in the age of peril," is able to devote increasing time to aerial weaponry of quality instead of "quantity" as dictated by war emergency.

## Research

At the basis of all of our aeronautical accomplishments is what we know about the laws of nature. Even the best equipped engineer can do
no more than apply the knowledge provided him by the scientist. Fundamental, or pure, research then sets the pace of technical progress.

Research has to do primarily with the discovery of new facts about nature and with finding and developing principles. Its aim is the ad-

[^34][^35]vancement of the frontiers of knowledge and the collection of basic information.

## Development

Development is the intricate process by which new knowledge is used by engineering and industry.

Application of the results of research to the design, development, and production of improved aircraft is a function of the aircraft industry. The industry's task is the design and production of aircraft with

Cost of Research as a Percentage of Sales, by Industry 1951

| Industry | Percent |
| :---: | :---: |
| All Industries | 2.0 |
| Manufacturing. | 2.0 |

a specified performance-so fast, so high, so far, so much capacitybased on military or civil requirements.

## Measuring the Research and Development Effort

At the beginning of the Second World War the annual outlay for all research and development in the United States was well below one billion dollars.

In 1952, it had risen to more than 3.5 billion dollars. About one half of this money came from the Federal Government.

Only about one-fourth of the government's research and development work was performed in government-owned installations. The rest went to industry, universities, research institutions, etc.

Research and development expenditures by the aircraft industry alone in 1951 (the only year for which information is available) totaled more than 400 million dollars. About six of every seven dollars spent on aircraft research and development in that year came from Federal funds.

In January, 1952, the aircraft industry employed more than 20,000 of the 90,000 professional research engineers and scientists, and 50,000 of the 220,000 total research personnel employed by American industry.

Research Personnel in Industry
January 1952

| Industry | Research <br> Engineers and Scientists | Total Research Employees |
| :---: | :---: | :---: |
| All Industries | 91,585 | 220,157 |
| Manufacturing. | 80,306 | 196,517 |
| Aircraft and Parts. | 20,235 | 49,915 |
| Electrical Machinery. | 17,274 | 51,172 |
| Chemicals and Allied Products. . . . . . | 13,201 | 23,211 |
| All Other Manufacturing............ | 29,596 | 72,219 |
| Non-Manufacturing. . . . . . . . . . . . . . . | 11,279 | 23,640 |

Sources: 72, 73.
The unusual concentration of the aircraft industry on research and development is also apparent in its employment of research personnel. While the industry employs only five percent of all employees in manufacturing industries, it employs 25 percent of all research engineers and scientists.

## AVA

THE AIRCRAFT INDUSTRIES ASSOCIATION

[^0]:    E Estimate.

[^1]:    The cost of now machines and buildings in the recent expansion, which began with the Korean buildup, almost equalled that of the Second World War. The aircraft industry provided a third of the funds for expansion. By January, 1955, facilities expansion was virtually completed.

[^2]:    a Total for last three quarters of 1948 only.

[^3]:    The aviation products charted represent the sales of some 50 major manufacturers of complote aircraft, complete aircraft engines, and complete aircraft propellers. Because other manufacturers also sell some aviation products directly to users, total sales actually are much larger than shown here.

[^4]:    © Small business concerns are those having less than 500 employees.
    Source: 86.

[^5]:    U.S. aircraft engine manufacturers for the first time, in 1954, began producing more jet than piston engines. Airframe manufacturers are building 91 different models of aircraft. Of this number 65 are military types and about half of these are jet powered.

[^6]:    N.A.-Not available.
    a The injury frequency rate is the average number of disabling work injuries for each million employee-hours worked.

    The severity rate is the average number of days lost as a result of disabling work injuries for each 1,000 employee-hours worked. The computations of days lost include standard time charges for fatalities and permanent disabilities.
    ${ }^{\circ}$ Included with "Aircraft."
    Sources: 68, 74.
    The aircraft industry is one of the safest industries in which to work. Continual employee education in safety habits has brought the industry far below the (all industry) average.

[^7]:    E Eatimate.
    N.A.-Not available.

[^8]:    E Estimate.
    N.A.-Not available.

    Sources: $2,69,70$.

[^9]:    *Prior to 1937 all corporations producing aircraft; 1937 to dato, twolve major airframe

[^10]:    or Gredit.
    Figures in parentheses indicate loss.
    Sources: 5, 6.

[^11]:    a Includes USAF acceptances for Navy, excludes Navy acceptances for USAF and Army.
    ${ }^{6}$ Includes USAF acceptances for other agencies. The duplicstion in acceptances accounts partly fo the difference between this table and the table on page 9.

[^12]:    *Salton Sea, Calif., Oct. 29, 1953.
    Sources: 11, 46.
    Maintaining American air supremacy, in peace and in war, is the principal means of assuring the national security. The United States aircraft industry in continual research effort strives unceasingly to improve performance aspects of its products. These are: speed, range, rate of climb, cargo capacity, ceiling, maneuverability. This table shows the progress of two types of planes in the short span of ten years.

[^13]:    ${ }^{a}$ Navy and Marine.

[^14]:    ${ }^{6} \mathrm{As}_{s}$ of November 1.

    - As of November 11.

    Sources: 8, 9.

[^15]:    E Estimate.

[^16]:    E Estimate.
    M Military Functions only; 1954 total includes Military Functions and Mutual Defense Assistant Programs.

[^17]:    E Estimate.
    N.A.-Not available.

    Sources: 2, 32, 38, 61.

[^18]:    - Includes commutation and electrified divisions of steam railway companies, but excludes electric railways.
    ${ }^{\circ}$ Negligible.
    Sources: 13, 15, 29, 32, 61.
    Almost the entire growth in passenger travel has been due to two modes of travel-automobiles and airlines. The growth of air traffic has been enormous. Yet, because air travel is still limited to medium and long distance travel (see average length of trip, p. 63), highways carry the bulk of passenger travel.

    ## The Ten Leading Passenger Transport Companies, 1954 (Millions of Revenue Passenger Miles ${ }^{a}$ )

    Pennsylvania Railroad ..... 3,447
    American Airlines ..... 3,372
    United Air Lines ..... 3,135
    New York Central System ..... 3,041
    Eastern Air Lines ..... 2,847
    Trans World Airlines ..... 2,611
    Atchison, Topeka \& Santa Fe Railway System ..... 1,948
    Union Pacific Railroad Company ..... 1,459
    Southern Pacific Company ..... 1,342
    New York, New Haven \& Hartford Railroad Company ..... 1,274

[^19]:    a Excludes commuters and multiple ride passengers.
    Sources: 38, 61.
    Four of the ten leading passenger carriers are U.S. airlines. In 1955, American Airlines is expected to be the largest carrier in the country. The figures exclude commuter data.

[^20]:    E Estimato.
    Sources: 2, 62.

[^21]:    Sources: 32, 35.

[^22]:    N.A.-Not available.

[^23]:    Source: 58.

[^24]:    N.A.-Not available.
    ${ }^{a}$ Civil airplane production shown here differs from that on $\mathrm{pp} 8 \& 9$. Recent OAA revision of total civil airplane production not yet carried through all breakdowns.

    Sources: 23, 32.
    Civil aircraft production has recovered from the low of 1951. Production now is mostly of larger multi-engine executive type planes as compared with the predominantly I-2 seat single-engine type production immediately following the end of the war.

[^25]:    E Estimate.
    N.A.-Not available.
    ${ }^{a}$ Airline Transport Rating became effective May 5, 1932.
    ${ }^{\circ}$ As of April 1, 1948.
    ${ }^{\circ}$ As of May 1, 1949.
    ${ }^{d}$ No survey made.
    ${ }^{\circ}$ As of July 1, 1954.
    ${ }^{\prime}$ July 1, 1953-June $30,1950$.
    Sources: 2, 32, 35.

[^26]:    ${ }^{a}$ Includes contract, industrial, and commercial agricultural flying.
    Oncludes flying for corporate or executive purposes as well as flying on personal business.
    ${ }^{c}$ Company Business 2.1 million hours; Individual Business 1.0 million hours.
    Source: 81.

[^27]:    *Pronunciation of the name helicopter is derived from the Greek-helix-meaning "spiral" and pteron-meaning "wing"-the accepted pronunciation is hell-i-copter.

[^28]:    ${ }^{a} A_{B}$ of Dcember 31.

[^29]:    N.A.-Not available.

[^30]:    a Under $400 \mathrm{~h} . \mathrm{p} . ;$ data for exports of engines of $400 \mathrm{~h} . \mathrm{p}$. and over withheld for "security reasons."
    ${ }^{\circ}$ Under 250 hp .
    Source: 23.

[^31]:    ${ }^{a}$ Revised. Since revision of previously reported monthly shipments is not available "Total" does not agree with total shipments reported above.
    ${ }^{\circ}$ Total shipments October 6, 1949 to September 30, 1951.
    Sources: 44, 45.

[^32]:    ${ }^{a}$ Less than .05 percent.
    Sources: 26, 27, 28, 29, 30.

[^33]:    a Less than $\$ 500,000$.

[^34]:    E Estimate.
    Sources: 49, 81.

[^35]:    It is estimated that the 2 billion dollar expenditures of the Federal government for research and development represent approximately half the total expenditures of the nation-industry spending another $\$ 2$ billions for this purpose. Eighty-five per cent of the Federal total goes to Defense and Atomic Energy.
